

# Sediment and Phosphorus TMDLs for Benthic Impairments in Little Otter River, Johns Creek, Wells Creek, and Buffalo Creek Bedford City, Bedford and Campbell Counties, Virginia

---

Submitted by:  
Virginia Department of Environmental Quality

Prepared by:  
Virginia Tech Department of Biological Systems Engineering

Revised Draft: December 18, 2013

---

VT-BSE Document No. 2013-0001

## **Project Personnel**

### **Virginia Tech, Department of Biological Systems Engineering (BSE)**

Gene Yagow, Sr. Research Scientist

Karen Kline, Research Scientist

Brian Benham, Associate Professor and Extension Specialist

### **Virginia Department of Environmental Quality (DEQ)**

Mary Dail, Blue Ridge Region TMDL Coordinator

Paula Nash, Blue Ridge Region TMDL Coordinator

Drew Miller, Blue Ridge Region Biologist

Sandra Mueller, Central Office

### **Virginia Department of Conservation and Recreation (DCR)**

Heather Vereb Longo, TMDL/Watershed Field Coordinator, Christiansburg

### **For additional information, please contact:**

#### **Virginia Department of Environmental Quality**

Water Quality Assessment Office, Richmond: Sandra Mueller (804) 698-4324

Blue Ridge Region Office, Roanoke: Mary Dail, (540) 562-6715

## Table of Contents

<b>EXECUTIVE SUMMARY.....</b>	<b>ES-1</b>
1.1. Introduction.....	ES-1
1.1.2. Applicable Water Quality Standard and Designated Use .....	ES-4
1.2. Benthic Stressor Analysis.....	ES-4
1.3. Accounting for Critical Conditions and Seasonal Variations .....	ES-7
1.4. Sediment Modeling Approach .....	ES-7
1.5. Model Calibration of Hydrology .....	ES-8
1.6. Simulated Sediment Loads.....	ES-9
1.6.1. Existing Sediment Loads .....	ES-9
1.6.2. Future Sediment Loads.....	ES-9
1.7. The Sediment TMDLs.....	ES-10
1.8. Allocation Scenarios .....	ES-12
1.9. Total Phosphorus Modeling Approach.....	ES-16
1.10. Model Calibration for Total Phosphorus .....	ES-18
1.11. Simulated Total Phosphorus Loads.....	ES-18
1.11.1. Existing Total Phosphorus Loads.....	ES-18
1.11.2. Future Total Phosphorus Loads.....	ES-19
1.12. The Total Phosphorus TMDL.....	ES-20
1.13. Allocation Scenarios .....	ES-21
1.14. Reasonable Assurance for Implementation.....	ES-22
<b>CHAPTER 2: INTRODUCTION .....</b>	<b>1</b>
2.1. Background .....	1
2.1.1. TMDL Definition and Regulatory Information .....	1
2.1.2. Impairment Listing.....	1
2.1.3. Pollutants of Concern.....	4
2.2. Designated Uses and Applicable Water Quality Standards .....	4
2.2.1. Designation of Uses (9 VAC 25-260-10) .....	4
2.2.2. General Standard (9 VAC 25-260-20).....	5
<b>CHAPTER 3: WATERSHED CHARACTERIZATION .....</b>	<b>7</b>
3.1. Water Resources.....	7
3.2. Eco-region .....	7
3.3. Soils and Geology .....	8
3.4. Climate .....	9
3.5. Land Use .....	9
3.6. Biological Monitoring Data - Benthic Macro-invertebrates .....	13
3.7. Biological Monitoring Data - Habitat .....	27
3.8. Water Quality Data .....	31
3.8.1. DEQ Ambient Monitoring Data.....	31
3.8.2. DEQ Stream Tests for Metals and Organic Compounds.....	42
3.8.3. DEQ - Other Relevant Monitoring or Reports.....	48
3.8.4. Permitted Point Sources .....	49
3.8.5. VAHWQP Household Drinking Water Analyses.....	51
3.8.6. Big Otter River Bacteria TMDL and Implementation Plan .....	52
3.8.7. Recent Implementation of Best Management Practices (BMPs).....	52
3.8.8. Lynchburg College Studies on Timber Lake .....	54

3.8.9. Citizen Monitoring Data from Timberlake Homeowner's Association (THA) .....	55
<b>CHAPTER 4: BENTHIC STRESSOR ANALYSIS.....</b>	<b>58</b>
4.1. Introduction.....	58
4.2. Stressor Analyses Summaries .....	59
<b>CHAPTER 5: SETTING REFERENCE TMDL LOADS .....</b>	<b>61</b>
5.1. Sediment .....	61
5.1.1. Selection of Local Comparison Watersheds .....	61
5.2. Total Phosphorus .....	63
<b>CHAPTER 6: MODELING PROCESS FOR TMDL DEVELOPMENT .....</b>	<b>65</b>
6.1. Model Selection.....	65
6.2. GWLF Model Development for Sediment.....	67
6.3. GWLF Model Development for Total Phosphorus .....	68
6.4. Input Data Requirements.....	70
6.4.1. Climate Data .....	70
6.4.2. Existing Land Use .....	71
6.5. Future Land Use.....	73
6.6. GWLF Parameter Evaluation.....	74
6.6.1. Hydrology Parameters .....	75
6.6.2. Sediment Parameters .....	76
6.6.3. Nutrient Parameters.....	77

## List of Acronyms

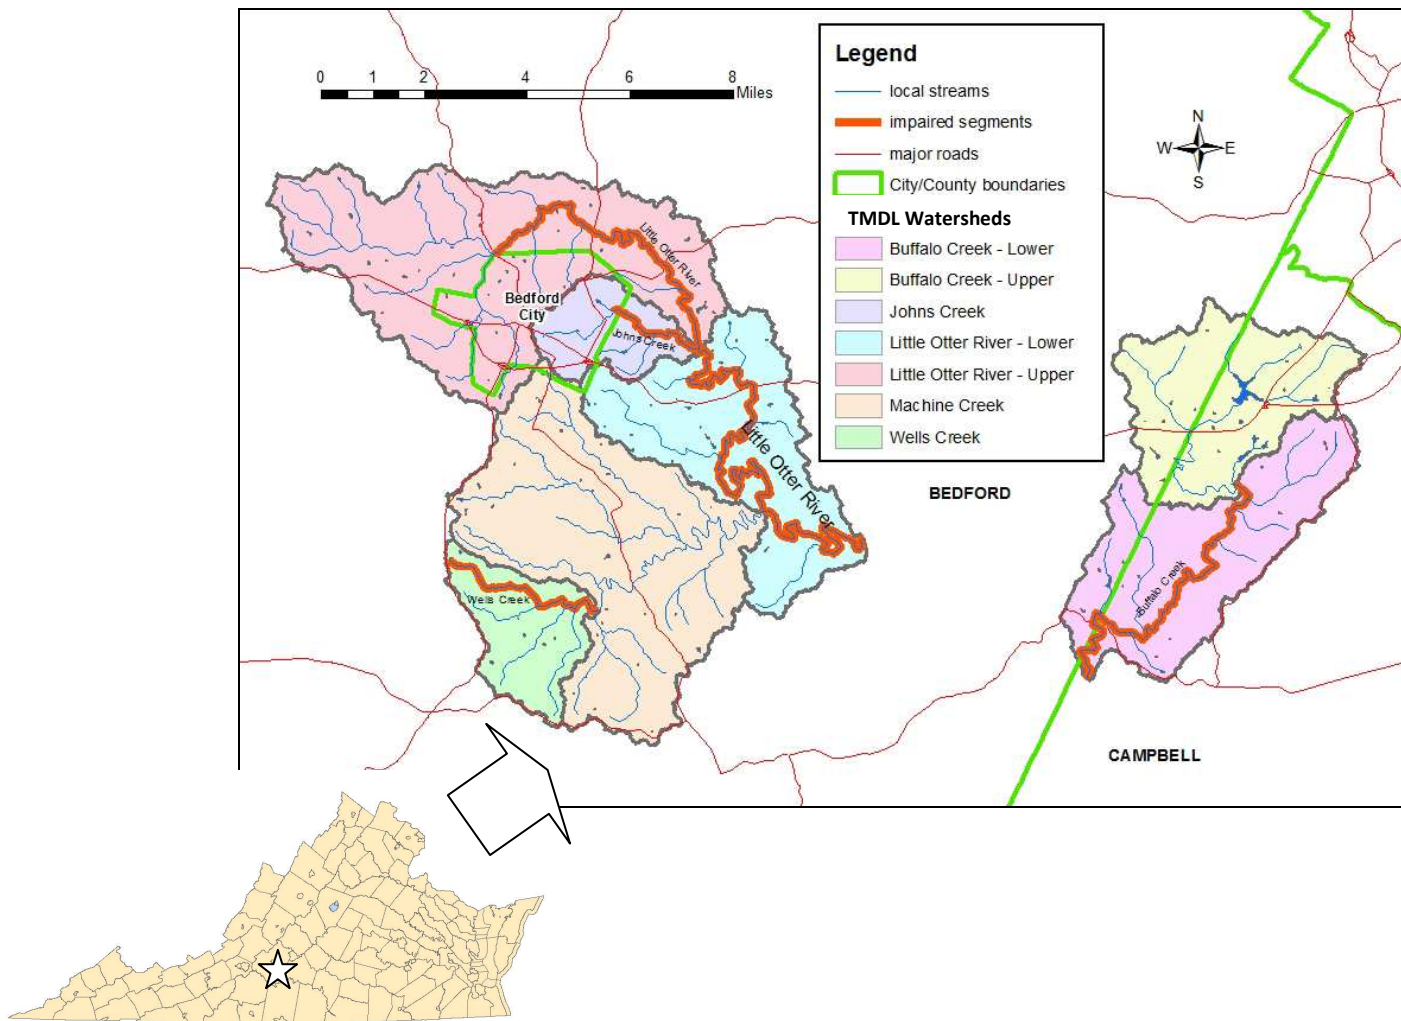

BMP	Best Management Practices
BSE	Biological Systems Engineering
CBWM	Chesapeake Bay Watershed Model
COD	Chemical Oxygen Demand
CV	Coefficient of variation
DCR	Virginia Department of Conservation and Recreation
DEQ	Virginia Department of Environmental Quality
DO	Dissolved Oxygen
E&S	Erosion and Sediment Control Program (DCR)
GIS	Geographic Information Systems
LA	Load Allocation
MDL	Minimum Detection Limit, also Maximum Daily Load
MFBI	Modified Family Biotic Index
MOS	Margin of Safety
MS4	Municipal Separate Storm Sewer System program (EPA)
NASS	National Agricultural Statistics Service (USDA)
NLCD	National Land Cover Dataset
NPS	Non-Point Source
NRCS	Natural Resources Conservation Service (USDA)
PEC	Probable Effect Concentrations
PReP	Pollution Response Program (DEQ)
RBP	Rapid Bioassessment Protocol
TDS	Total Dissolved Solids
THA	Timberlake Homeowners Association
TKN	Total Kjeldahl Nitrogen
TMDL	Total Maximum Daily Load
TN	Total Nitrogen
TP	Total Phosphorous
TSS	Total Suspended Solids
USDA	United States Department of Agriculture
USEPA	United States Environmental Protection Agency
VSCI	Virginia Stream Condition Index
VPDES	Virginia Pollutant Discharge Elimination System
VSMP	Virginia Stormwater Management Program (DCR)
VT	Virginia Tech
WIP	Watershed Implementation Plan
WLA	Waste Load Allocation

# EXECUTIVE SUMMARY

## 1.1. Introduction

Section 303(d) of the Federal Clean Water Act and the U.S. Environmental Protection Agency's (USEPA) Water Quality Planning and Management Regulations (40 CFR Part 130) require states to identify water bodies that violate state water quality standards and to develop Total Maximum Daily Loads (TMDLs) for such water bodies. A TMDL reflects the pollutant loading a water body can receive and still meet water quality standards. A TMDL establishes the allowable pollutant loading from both point and nonpoint sources for a water body, allocates the load among the pollutant contributors, and provides a framework for taking actions to restore water quality.

The subjects of this TMDL study are eight impaired stream segments in two neighboring watersheds: four segments on Little Otter River; one segment each in Johns Creek and Wells Creek, both tributary to Little Otter River; and two segments on Buffalo Creek. These impaired segments are located within the Roanoke River Basin within Bedford City and Bedford and Campbell Counties in the Commonwealth of Virginia, Figure ES-0-1. The watersheds delineated to simulate sediment loading to these impaired segments are also shown in the figure and will herein be referred to as the sediment TMDL watersheds. Johns Creek and the Upper Little Otter River watersheds were also used to simulate total phosphorus loading to the upper portion of the Lower Little Otter River.

**Figure ES-0-1. Location of Impaired Segments and TMDL Watersheds**

### Little Otter River

Little Otter River receives flow from both the Johns Creek and Wells Creek tributaries. The Little Otter River stream segment above the confluence with Johns Creek is referred to in this report as the Upper Little Otter River, and the Little Otter River stream segment between the confluence with Johns Creek and its downstream confluence with Big Otter River is referred to as Lower Little Otter River. Wells Creek is tributary to Machine Creek, which is tributary to the Lower Little Otter River.

The Upper Little Otter River was originally listed as impaired due to water quality violations of the general aquatic life (benthic) standard in the 2002 Virginia

303(d) Report (VADEQ, 2002). This impairment was based on biological monitoring at station 4ALOR014.75 and extended 5.71 miles upstream from its confluence with Johns Creek. In 2008, an additional 1.58 miles of stream was listed as impaired, extending upstream from the previous impairment for a total of 7.29 miles to its headwaters. In 2010, an impairment on the entire Lower Little Otter River (14.33 miles) was added based on the monitoring at stations 4ALOR012.20, 4ALOR008.64, and 4ALOR007.20, for a total combined impaired length on the Little Otter River of 21.62 miles. These impairments comprise DEQ's Cause Group Code L26R-01-BEN and consist of 4 impaired segments (VAW-L26R\_LOR01A00, LOR02A00, LOR03A00, and LOR04A00). The Upper Little Otter River shows habitat impacts from sediment deposition in stream, eroded stream banks, and removal of vegetation in the riparian zone. The Lower Little Otter River shows similar habitat impacts with stream substrates embedded with fine sediments and eroding stream banks.

Johns Creek was originally listed with a benthic impairment in 2002 based on monitoring at station 4AJHN000.01. Johns Creek was listed for its entire length of 2.13 miles, from its headwaters to its confluence with Little Otter River. This impairment is listed as DEQ's Cause Group Code L26R-02-BEN and consists of just one impaired segment, VAW-L26R\_JHN01A00. The stream is affected by urban and agricultural NPS pollution and flashy flows, which contribute to the erosion of its stream banks.

Wells Creek was listed initially with a benthic impairment in 2008 based on monitoring at station 4AWEL000.59. Wells Creek was listed for its entire length 3.78 miles, from its headwaters to its confluence with Machine Creek. This impairment is listed as DEQ's Cause Group Code L26R-03-BEN and consists of just one impaired segment, VAW-L26R\_WEL01A02. The stream is affected by narrow riparian buffer zones and stream bank erosion, which contribute to deposition of fine sediment in the stream.

## Buffalo Creek

Buffalo Creek was originally listed as impaired due to water quality violations of the general aquatic life (benthic) standard in the 2008 Virginia Water Quality Assessment 305(b)/303(d) Integrated Report (VADEQ, 2008).

The Virginia Department of Environmental Quality (DEQ) has identified this impairment as Cause Group Code L27R-02-BEN, and delineated the benthic impairment as 8.09 miles on Buffalo Creek (stream segments VAC-L27R\_BWA01A00 and VAC-L27R\_BWA02A02). The Buffalo Creek impaired segments are contiguous and begin at an unnamed tributary at the Route 811 crossing in Campbell County and extend to the confluence with the Big Otter River.

The DEQ 2008 Fact Sheets for Category 5 Waters (VADEQ, 2008) state that Buffalo Creek is impaired based on assessments at biological station 4ABWA008.53. The source of impairment is described as related to the surrounding residential land uses with “increasing sedimentation and flashy flows causing erosion and nutrient enrichment.”

### **1.1.2. Applicable Water Quality Standard and Designated Use**

Pollution from both point and nonpoint sources can lead to a violation of Virginia’s General Standard (9 VAC 25-260-20). A violation of this standard is assessed on the basis of measurements of the in-stream benthic macro-invertebrate community. Water bodies having a benthic impairment are not fully supportive of the aquatic life designated use for Virginia’s waters (9 VAC 25-260-10).

## **1.2. Benthic Stressor Analysis**

TMDLs must be developed for a specific pollutant. Since a benthic impairment is based on a biological inventory, rather than on a physical or chemical water quality parameter, the pollutant is not explicitly identified in the assessment, as it is with physical and chemical parameters. The process outlined

in USEPA's Stressor Identification Guidance Document (USEPA, 2000) was used to identify the critical stressors for the impaired stream segments in this study.

The Upper Little Otter River (VAW-L26R\_LOR04A00) stream segment is impaired, but the trend is positive with 2 out of 4 recent individual VSCI sample scores being in the "non-impaired" range. The Upper Little Otter River is impacted by a combination of urban and agricultural land uses. Sediment was selected as the most probable stressor based on the poor stream bank habitat scores and the evidence given by the relative bed stability analysis indicating excessive sediment contributions from anthropogenic sources.

The Johns Creek (VAW-L26R\_JHN01A00) stream segment was severely impaired for its aquatic life use between 1997 and 2008, but has been gradually improving. Johns Creek is impacted by a combination of urban and agricultural land uses. Sediment was selected as the most probable stressor based on consistently poor scores of the habitat sediment metrics.

The Wells Creek (VAW-L26R\_WEL01A02) stream segment shows impairment for its aquatic life use primarily in the springtime samples, with the most recent individual VSCI sample score in the fall being in the "non-impaired" range. Wells Creek is impacted primarily by agricultural land uses. Sediment was selected as the most probable stressor based on the poor habitat sediment metric scores and the evidence given by the LRBS analysis indicating excessive sediment contributions from anthropogenic sources.

The Lower Little Otter River (VAW-L26R\_LOR01A00, VAW-L26R\_LOR02A00, VAW-L26R\_LOR03A00) stream segments are impaired for their aquatic life use, with the degree of impairment decreasing over time and from upstream to downstream, although the most recent samples have once again shown signs of stress. The Lower Little Otter River is impacted primarily by total phosphorus (TP) from the WWTP effluent discharge, and by sediment coming from a combination of upstream impaired segments, in-stream bank and channel erosion, and land disturbance in the immediate watershed. Although the WWTP is not monitoring for TP at this time, it is bracketed by DEQ monitoring stations within a half mile of each other, which show increased TP concentrations

at the downstream station with no other plausible source. Therefore, the most probable stressors in this segment are both TP and sediment, with TP primarily and apparently related to WWTP effluent discharge.

The Buffalo Creek (VAC-L27R\_BWA01A00, VAC-L27R\_BWA02A02) stream segments are impaired for aquatic life use, with lower biological index scores in the upstream segment and with some recovery in the downstream segment, whose watershed is predominantly forested. Buffalo Creek is impacted by both urban/residential development and agricultural land uses. Sediment was selected as the most probable stressor based on the low upstream LRBS score, livestock with stream access, and the presence of many other land-disturbing activities.

Therefore, sediment TMDLs will be developed to address the biological impairments in Upper Little Otter River, Johns Creek, Wells Creek, the Lower Little Otter River, and Buffalo Creek.

The total phosphorus impairment in the Lower Little Otter River is heavily influenced by discharge from the Bedford City WWTP. Permit limits on total phosphorus for the WWTP have been recommended, after analysis of preliminary modeling and in consultation with state and regional DEQ personnel.

In addition to the benthic impairments, the watersheds contributing to these impaired stream segments are part of the larger Big Otter River watershed, which also has a bacteria impairment addressed during a previously developed TMDL (Mostaghimi et al., 2000) and implementation plan (VT-BSE, 2006 ). Pollutant sources which were identified to affect the bacteria load reductions in the bacteria TMDL will also affect loads from stressors identified for the aquatic life use impairment. In particular, the bacteria TMDL calls for reductions of 85% from bacteria loads on cropland and pasture and 30% reduction from livestock with direct stream access. Since the bacteria reductions from cropland and pasture loads relate primarily to livestock manure, they will also reduce nutrient loads from these sources. The livestock exclusion BMP will further reduce loads of nutrients and sediment.

### **1.3. Accounting for Critical Conditions and Seasonal Variations**

EPA regulations at 40 GFR 130.7 (c)(1) require TMDLs to take into account critical conditions for stream flow, loading, and water quality parameters. These conditions were considered in this study through the use of long-term (19 years) rainfall and temperature inputs to the model that covered different flow regimes and weather variability.

The GWLF model used for simulating both sediment and total phosphorus in the various impaired watersheds is a continuous simulation model that uses daily time steps for weather data and water balance calculations. The period of rainfall selected for modeling was chosen as a multi-year period that was representative of typical weather conditions for the area, and included “dry”, “normal” and “wet” years. The model, therefore, incorporated the variable inputs needed to represent critical conditions during low flow - generally associated with point source loads - and critical conditions during high flow - generally associated with nonpoint source loads.

The GWLF model used for this analysis considered seasonal variation through a number of mechanisms. Daily time steps were used for weather data and water balance calculations. The model also used monthly-variable parameter inputs for evapo-transpiration cover coefficients, daylight hours/day, and rainfall erosivity coefficients for user-specified growing season months. Post-processing was also used to incorporate variable monthly flow recorded by the WWTP in its Discharge Monitoring Reports to DEQ.

### **1.4. Sediment Modeling Approach**

A key component in developing a TMDL is establishing the relationship between pollutant loadings (both point and nonpoint) and in-stream water quality conditions. In the development of the sediment TMDLs for the Little Otter River and Buffalo Creek watersheds, the relationship between pollutant sources and pollutant loading to the stream was defined by land uses and areas assessed

from the NASS 2009 cropland data layer, together with non-land based loads and simulated output from a computer watershed loading model.

The model selected for development of the sediment TMDLs in the Little Otter River and Buffalo Creek watersheds was the Generalized Watershed Loading Functions (GWLF2010) model, as modified by Yagow. The model was run in metric units and converted to English units for this report.

The six impaired segments and the TMDL watersheds used for simulating sediment loads are shown in Figure ES-0-2.

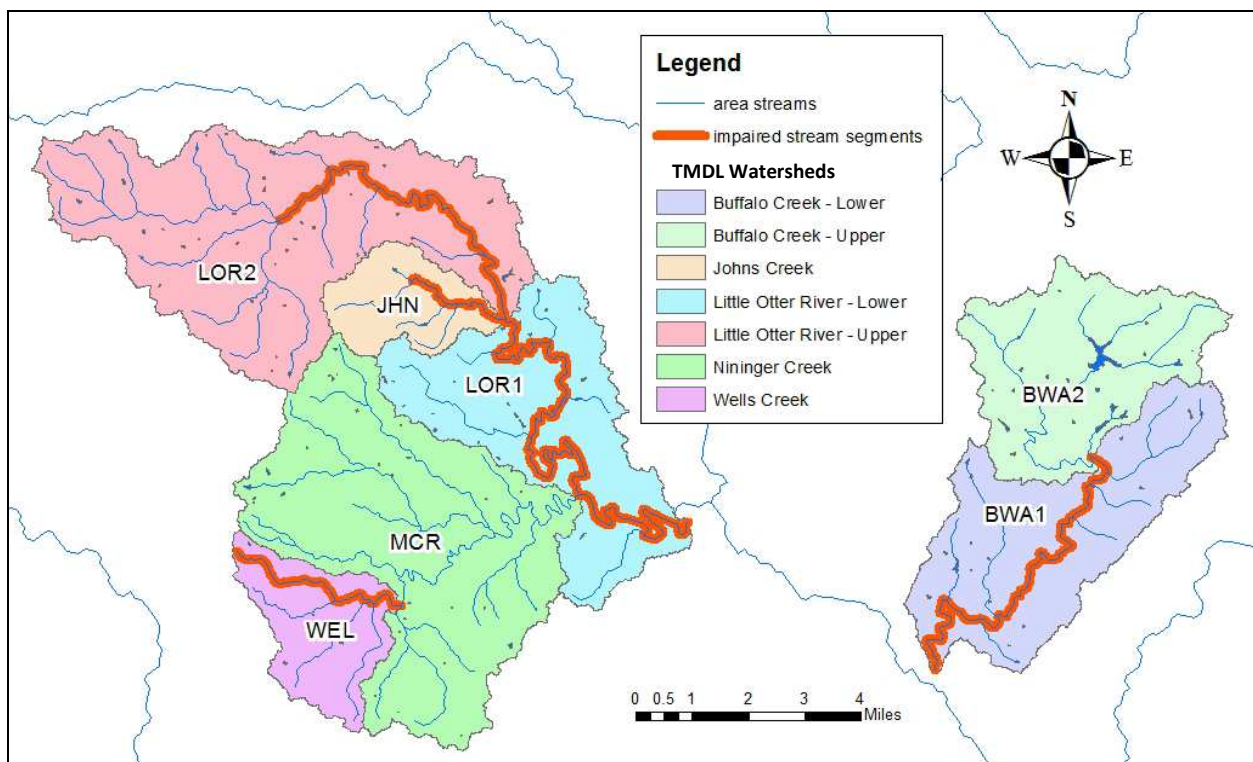

Figure ES-0-2. TMDL Watersheds in Little Otter River and Buffalo Creek

## 1.5. Model Calibration of Hydrology

Model calibration is the process of adjusting model parameter values so that simulated loads from a watershed match loads calculated from corresponding monitored (“observed”) flow and concentrations at a given point in a stream. Although GWLF was originally developed for use in non-gaged watersheds and, therefore, does not require calibration, hydrologic calibration has been recommended where observed flow data is available (Dai et al., 2000).

In-stream observed discharge data were not available in any of the Little Otter River or Buffalo Creek sub-watersheds, but were available in a similar-sized neighboring watershed, the Big Otter River. Hydrologic calibration was performed using this surrogate watershed, and the calibration adjustments applied to all of the Little Otter River, Buffalo Creek and comparison watersheds for the TMDL modeling.

## 1.6. Simulated Sediment Loads

### 1.6.1. Existing Sediment Loads

Existing sediment loads were simulated for all individual land uses with the calibrated GWLF model and calculated for point sources from monitored data. The resulting loads in all TMDL and comparison watersheds are given in Table ES-1.

**Table ES-1. Existing Sediment Loads in TMDL and Comparison Watersheds**

Land Use/Source Categories	TMDL Watersheds							Comparison Watersheds

### 1.6.2. Future Sediment Loads

Future sediment loads were simulated for all land use categories with the calibrated GWLF model with point sources calculated at their permit limits. Since

future sediment loads are considered to be the starting loads from which reductions will be required to meet the TMDLs, modeling of the future land uses was only performed on the TMDL watersheds. The resulting future loads of sediment, shown in Table ES-2 are simulated after assessing future land use changes from agriculture and forest land uses to developed land uses.

**Table ES-2. Future Sediment Loads in TMDL Watersheds**

## 1.7. The Sediment TMDLs

The stressor analysis in the Buffalo Creek and Little Otter River watersheds indicated that sediment was the “most probable stressor”, and therefore, sediment served as the basis for development of these TMDLs.

Since there are no in-stream water quality standards for sediment in Virginia, an alternate method was needed for establishing a reference endpoint that would represent the “non-impaired” condition. For the Little Otter River and Buffalo Creek impairments, Maryland’s methodology for addressing sediment impairments was modified to create the all-forest load multiplier (AllForX)

approach, which was used to set the sediment TMDL endpoint and to quantify the MOS for each TMDL (see Appendix F for details).

The sediment TMDL for the Buffalo Creek and Little Otter River watersheds was calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

where  $\sum \text{WLA}$  = sum of the wasteload (permitted) allocations;

$\sum \text{LA}$  = sum of load (nonpoint source) allocations; and

MOS = margin of safety.

The TMDL and explicit MOS sediment loads for each TMDL watershed were calculated using the all-forest load multiplier (AllForX) method. AllForX is the ratio of GWLF modeled loads: the existing condition load divided by an all-forest condition load from the same watershed. A regression was developed between AllForX and the Virginia Stream Condition Index (VSCI) for a combination of TMDL and nearby healthy watersheds. The TMDL load for the impaired watershed is calculated as its all-forest load times the value of AllForX at the point along the regression line where the VSCI = 60. The MOS was calculated explicitly from the lower limits of the 80% confidence interval surrounding the selected AllForX value.

The WLA in each watershed is comprised of sediment loads from a number of individual industrial stormwater, municipal, and commercial permitted sources, as well as aggregated loads from construction runoff in each watershed. In addition, a Future Growth WLA was calculated as a portion of existing WLAs in each watershed, excluding construction, plus a portion of existing WWTP WLAs, with a minimum allowance of 0.1% of the TMDL.

The LA was calculated as the TMDL minus the sum of WLA and MOS. The TMDL load and its components for each TMDL watershed are shown in Table ES-3.

## 1.8. Sediment Allocation Scenarios

The target sediment load for each watershed allocation scenario is the TMDL minus the MOS. Allocation scenarios were created by applying percent reductions to the various land use/source categories until the target allocation

load was achieved for each of the Buffalo Creek and Little Otter River watersheds.

Two allocation scenarios were created for each of the watersheds. Scenario 1 applies equal percent reductions from all land uses and sources, except forest and point sources. Scenario 2 applies equal percent reductions from only the two largest sources in each watershed. These scenarios represent two strategies that can be refined by a local Implementation Planning committee, as they consider applicable BMPs, costs, and available funding sources for site-specific implementation. Future sediment loads and the two allocation scenarios are presented by grouped land uses and sources for the Lower Buffalo Creek in Table ES-4; Upper Buffalo Creek in Table ES-5; for the Lower Little Otter River in Table ES-6; for Johns Creek in Table ES-7; for Wells Creek in Table ES-8; and for the Upper Little Otter River in Table ES-9.

**Table ES-4. Sediment TMDL Load Allocation Scenario, Lower Buffalo Creek**

### 1.9. Total Phosphorus Modeling Approach

Total phosphorus modeling was essentially a mass balance approach with TP concentrations monitored at one station each on Johns Creek and the Upper Little Otter River, monitored discharge from the WWTP and a monitoring station on the Lower Little Otter River just below the confluence. The WWTP discharged flow and TP directly at the confluence, and the effect was measured at the third monitoring station immediately downstream from the confluence. Although the benthic impairment was shown at several stations along the Lower Little Otter River segments, the increases in TP loading were coming from upstream, as documented at the downstream station, 4ALOR014.33.

The TP impairment on the Lower Little Otter River was determined to originate primarily from excess loads from the Bedford City WWTP. Since the discharge from the WWTP was at the confluence of the Upper Little Otter River and Johns Creek, and since a DEQ monitoring station (4ALOR014.33) sits 100 yards downstream from the confluence, the TP TMDL for the Lower Little Otter River was developed for the watershed above station 4ALOR014.33 on the Lower Little Otter River. A diagram of the various DEQ monitoring station locations and that of the WWTP discharge point are shown in Figure ES-3.

**Figure ES-0-3. Locations of DEQ Monitoring Stations and the Bedford City WWTP**

Model development for all watersheds was performed by assessing the sources of phosphorus in the watershed, evaluating the necessary parameters for modeling loads, applying the hydrologic calibration parameter adjustments, and calibrating to average observed in-stream TP concentration data in each of the two upstream sub-watersheds above the WWTP, and finally applying the GWLF model and procedures for calculating loads. Since the area between the confluence of Johns Creek with the Upper Little Otter River and station 4ALOR014.33 was minimal (1 hectare) and primarily forested, the total phosphorus loads at station 4ALOR014.33 were represented as the sum of the loads from the Johns Creek (JHN) and Upper Little Otter River (LOR2) watersheds plus the load from the WWTP.

## **1.10. Model Calibration for Total Phosphorus**

Model calibration was performed separately on Johns Creek and on Upper Little Otter Creek. Observed in-stream TP concentration data were available at DEQ ambient monitoring stations 4AJHN000.01 on Johns Creek from May 2009 through November 2011 and at 4ALOR014.75 on the Upper Little Otter River from February 2007 through April 2012. Calibration was performed by adjusting the average simulated concentration (calculated as total TP load divided by total flow) for an 8-year period, 2004 through 2011, with the average observed concentration at each station.

## **1.11. Simulated Total Phosphorus Loads**

### **1.11.1. Existing Total Phosphorus Loads**

Existing TP loads were simulated for all individual land uses with the calibrated GWLF model, including existing BMPs and calculated loads for direct deposition and the WWTP. The resulting loads from the two component watersheds and the WWTP are given in Table ES-10.

**Table ES-10. Existing Total Phosphorus Loads above 4ALOR014.33**

Land Use/ Source Categories	Johns Creek	Upper Little Otter River	WWTP	Total
	Phosphorus Load (lbs/yr)			
HiTill Rowcrop (hit)	1.1	1.2		2.3

### 1.11.2. Future Total Phosphorus Loads

Future land use was represented as anticipated changes in acreage from agriculture and forestry to developed land uses, the same as for sediment. Future TP loads were simulated for all land use categories with the calibrated GWLF model, including existing BMPs, and calculated loads for direct deposition and the WWTP, Table ES-11.

**Table ES-11. Future Total Phosphorus Loads above 4ALOR014.33**

Land Use/ Source Categories	Johns Creek	Upper Little Otter River	WWTP	Total TP Load
	Phosphorus Load (lbs/yr)			
HiTill Rowcrop (hit)	0.11	0.23		0.3

## 1.12. The Total Phosphorus TMDL

The total phosphorus TMDL for the Lower Little Otter River watershed above station 4ALOR014.33 was calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

where  $\sum \text{WLA}$  = sum of the wasteload (permitted) allocations;

$\sum \text{LA}$  = sum of load (nonpoint source) allocations; and

MOS = margin of safety.

The TP TMDL load was calculated as the average annual load corresponding to an average annual in-stream concentration of 0.07 mg/L. This

endpoint was based on the 90<sup>th</sup> percentile concentration of a neighboring non-impaired watershed on the Big Otter River above station 4ABOR033.22.

Although there are currently no permitted sources of TP in the watershed, the recommendation is to add permit limits for TP to the Bedford City WWTP for an average annual TP concentration of 0.5 mg/L, consistent with effluent limits applied to significant municipal wastewater dischargers in the James River.

The MOS was considered to be implicit based on simulated loads calibrated to available in-stream monitoring data on both confluencing streams and the low coefficient of variation in simulated annual loads.

The LA was calculated as the TMDL minus the sum of WLA and MOS. The TMDL load and its components for the Lower Little Otter River watershed are shown in Table ES-12.

**Table ES-12. Lower Little Otter River Total Phosphorus TMDL**

<b>TMDL</b>	<b>WLA</b>	<b>LA</b>	<b>MOS</b>
<b>(lbs/yr)</b>			
3,655.6	1,523.0	2,132.6	0.0
	VA0022390 Bedford City - WWTP 1,523.0		

### **1.13. Total Phosphorus Allocation Scenario**

The target allocation TP load for the Lower Little Otter River at station 4ALOR014.33 in the allocation scenario is the TMDL minus the MOS. Progressive scenarios were developed to show the impact of planned BMPs on TP loads from the Big Otter bacteria Implementation Plan (VT-BSE, 2006), from reductions called for in the Little Otter River sediment TMDLs (this document), and from the proposed effluent limits for the Bedford City WWTP, which would lead to sufficient reductions to meet the in-stream concentration endpoint under current flow rates from the WWTP. Future TP loads along with progressive BMP reduction scenarios are presented in Table ES-13, along with two alternate Allocation Scenarios that satisfy the TMDL. Allocation Scenario 1 would satisfy the TMDL based on current average daily flow from the WWTP and a 0.5 mg/L

TP effluent limit. Allocation Scenario 2 meets the TMDL by allowing for expansion to the full design flow at the WWTP, but at a lower effluent limit (0.3 mg/L TP).

**Table ES-13. Progressive TP Reduction Scenarios at Station 4ALOR014.33**

Land Use / Source Groups	Units	Future TP Load	BMP Scenario 1	BMP Scenario 2	Allocation Scenario 1	Allocation Scenario 2
Row Crops	(lbs/yr)	4.9	4.9	4.9	4.9	4.9
Pasture		1,528.3	1,172.2	1,109.5	1,109.5	1,109.5
Hay		177.8	188.2	188.2	188.2	188.2
Forest		20.3	20.3	20.3	20.3	20.3
Harvested Forest		2.2	2.2	2.2	2.2	2.2
Developed		946.5	798.8	377.5	377.5	377.5
Channel Erosion		24.5	24.7	24.7	24.7	24.7
WWTP		7,083.8	7,083.8	7,083.8	1,523.0	1,827.62
Livestock Direct Deposit		22.9	0.0	0.0	0.0	0.0
Groundwater		265.9	265.9	265.9	265.9	265.9
<b>Total TP Load</b>		<b>10,077.2</b>	<b>9,561.0</b>	<b>9,077.1</b>	<b>3,516.3</b>	<b>3,820.9</b>
Total Flow Volume	(L x 10 <sup>6</sup> /yr)	23,687.3	23,475.3	23,466.3	23,466.3	24,850.7
<b>Average TP Concentration</b>	(mg/L)	<b>0.193</b>	<b>0.185</b>	<b>0.175</b>	<b>0.068</b>	<b>0.070</b>

BMP Scenario 1 = Future Load + all Big Otter River IP BMPs.

BMP Scenario 2 = BMP Scenario 1 + all Little Otter River sediment TMDL reductions.

Allocation Scenario 1 = BMP Scenario 2 + WWTP at current flow (1.0 MGD) and 0.5 mg/L TP effluent limit.

Allocation Scenario 2 = BMP Scenario 2 + WWTP at design flow (2.0 MGD) and 0.3 mg/L TP effluent limit.

### 1.14. Reasonable Assurance for Implementation

Several factors provide assurance that the TMDLs will be implemented. Virginia intends for the required sediment reductions to be implemented in an iterative process that addresses those sources with the largest impact on water quality. DEQ will continue to monitor benthic macro-invertebrates and habitat in accordance with its biological monitoring program, and TSS in accordance with its ambient monitoring program at station 4ALOR014.75 on the Upper Little Otter River, at station 4AJHN000.01 on Johns Creek, at station 4AWEL001.14 on Wells Creek, at station 4ALOR014.33 on the Lower Little Otter River, at station 4ABWA008.53 on the Upper Buffalo Creek, and at station 4ABWA002.00 on the

Lower Buffalo Creek. In the past, all of these stations have been used for both biological and ambient sampling, with the exception of stations 4ALOR014.33 and station 4ABWA008.53 which were monitored regularly for benthic macro-invertebrates and habitat, but only periodically for ambient parameters. DEQ will add bi-monthly sampling of ambient TSS at these two stations and will continue to use data from all of these monitoring stations to evaluate improvements in the benthic community and the effectiveness of TMDL implementation in attainment of the general water quality standard.

Additionally, a TMDL implementation plan will be developed and implemented in accordance with requirements of the Virginia's 1997 Water Quality Monitoring, Information and Restoration Act (WQMIRA).

Implementation of BMPs to address the benthic impairments in Buffalo Creek and Little Otter River will be coordinated with BMPs required to meet bacteria water quality standards in a previous TMDL developed for the Big Otter River watershed, which includes both Buffalo Creek and Little Otter River.

Public participation was elicited at every stage of the TMDL development in order to receive inputs from stakeholders and to apprise the stakeholders of the progress made. Three Technical Advisory Committee meetings and two public meetings were organized for this purpose.

The first Technical Advisory Committee Meeting was held on June 21, 2012 at the Bedford Central Library in Bedford, Virginia to introduce agency stakeholders to the TMDL process and to discuss the impairments identified on stream segments in these watersheds, followed by a watershed tour, conducted by personnel from the Peaks of Otter Soil and Water Conservation District and NRCS personnel. The final public meeting was held at the same location on February 20, 2013 to present the draft TMDL report to address benthic impairments in the Little Otter River and Buffalo Creek watersheds. The public comment period will end on March 22, 2013.

Since the TP TMDL for the Lower Little Otter River was developed after the final public meeting mentioned above, in lieu of remediation strictly through the permit process, another local Technical Advisory Committee was held on

December ??, 2013 to present the findings to key members of the watershed group, including representatives from the Bedford City municipal authority and to obtain feedback. This revised report, which includes the TP TMDL, will be distributed by email to all past attendees of public meetings and will be posted on DEQ's web site to solicit any additional public comments. The public comment period will end on January ??, 2014.

## **Chapter 2: INTRODUCTION**

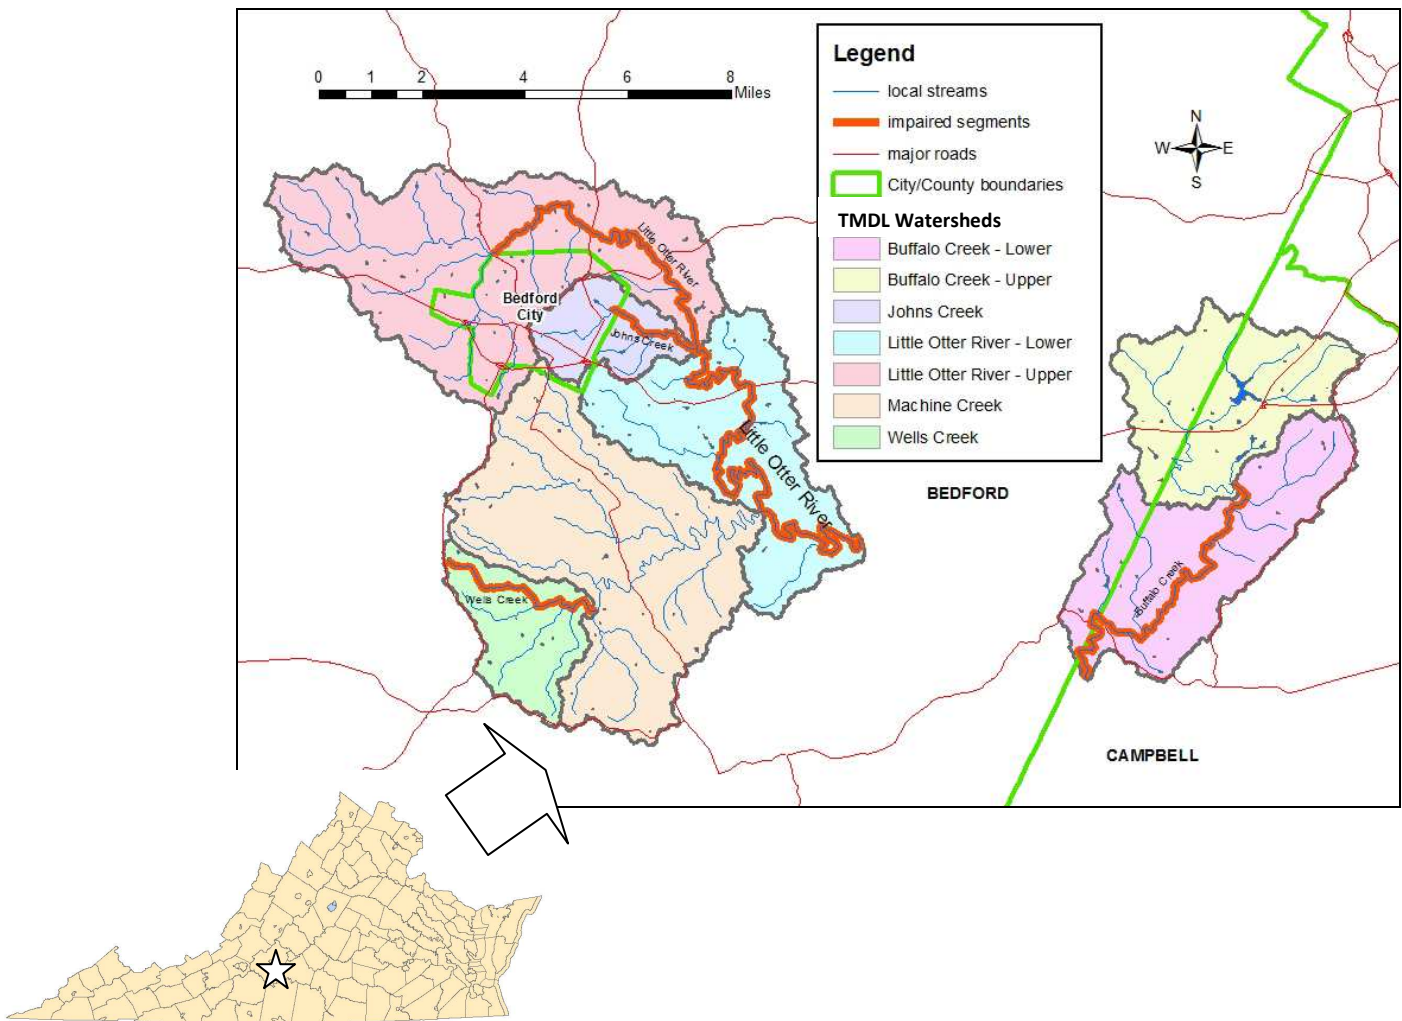

### **2.1. Background**

#### **2.1.1. TMDL Definition and Regulatory Information**

Section 303(d) of the Federal Clean Water Act and the U.S. Environmental Protection Agency's (USEPA) Water Quality Planning and Management Regulations (40 CFR Part 130) require states to identify water bodies that violate state water quality standards and to develop Total Maximum Daily Loads (TMDLs) for such water bodies. A TMDL reflects the pollutant loading a water body can receive and still meet water quality standards. A TMDL establishes the allowable pollutant loading from both point and nonpoint sources for a water body, allocates the load among the pollutant contributors, and provides a framework for taking actions to restore water quality.

#### **2.1.2. Impairment Listing**

The subjects of this TMDL study are eight impaired stream segments in two neighboring watersheds: four segments on Little Otter River; one segment each in Johns Creek and Wells Creek, both tributary to Little Otter River; and two segments on Buffalo Creek. These impaired segments are located within the Roanoke River Basin within Bedford City and Bedford and Campbell Counties in the Commonwealth of Virginia, . The watersheds delineated to simulate pollutant loads to these impaired segments are also shown in Figure 2-1 and will herein be referred to as the TMDL watersheds.

**Figure 2-1. Location of Impaired Segments and TMDL Watersheds**

### Little Otter River

Little Otter River receives flow from both the Johns Creek and Wells Creek tributaries. The Little Otter River stream segment above the confluence with Johns Creek is referred to in this report as the Upper Little Otter River, and the Little Otter River stream segment between the confluence with Johns Creek and its downstream confluence with Big Otter River is referred to as Lower Little Otter River. Wells Creek is tributary to Machine Creek, which is tributary to the Lower Little Otter River.

The Upper Little Otter River was originally listed as impaired due to water quality violations of the general aquatic life (benthic) standard in the 2002 Virginia

303(d) Report (VADEQ, 2002). This impairment was based on biological monitoring at station 4ALOR014.75 and extended 5.71 miles upstream from its confluence with Johns Creek. In 2008, an additional 1.58 miles of stream was listed as impaired, extending upstream from the previous impairment for a total of 7.29 miles to its headwaters. In 2010, an impairment on the entire Lower Little Otter River (14.33 miles) was added based on the monitoring at stations 4ALOR012.20, 4ALOR008.64, and 4ALOR007.20, for a total combined impaired length on the Little Otter River of 21.62 miles. These impairments comprise DEQ's Cause Group Code L26R-01-BEN and consist of 4 impaired segments (VAW-L26R\_LOR01A00, LOR02A00, LOR03A00, and LOR04A00). The Upper Little Otter River shows habitat impacts from sediment deposition in stream, eroded stream banks, and removal of vegetation in the riparian zone. The Lower Little Otter River shows similar habitat impacts with stream substrates embedded with fine sediments and eroding stream banks.

Johns Creek was originally listed with a benthic impairment in 2002 based on monitoring at station 4AJHN000.01. Johns Creek was listed for its entire length of 2.13 miles, from its headwaters to its confluence with Little Otter River. This impairment is listed as DEQ's Cause Group Code L26R-02-BEN and consists of just one impaired segment, VAW-L26R\_JHN01A00. The stream is affected by urban and agricultural NPS pollution and flashy flows, which contribute to the erosion of its stream banks.

Wells Creek was listed initially with a benthic impairment in 2008 based on monitoring at station 4AWEL000.59. Wells Creek was listed for its entire length 3.78 miles, from its headwaters to its confluence with Machine Creek. This impairment is listed as DEQ's Cause Group Code L26R-03-BEN and consists of just one impaired segment, VAW-L26R\_WEL01A02. The stream is affected by narrow riparian buffer zones and stream bank erosion, which contributes to deposition of fine sediment in the stream.

### Buffalo Creek

Buffalo Creek was originally listed as impaired due to water quality violations of the general aquatic life (benthic) standard in the 2008 Virginia Water Quality Assessment 305(b)/303(d) Integrated Report (VADEQ, 2008).

The Virginia Department of Environmental Quality (DEQ) has identified this impairment as Cause Group Code L27R-02-BEN, and delineated the benthic impairment as 8.09 miles on Buffalo Creek (stream segments VAC-L27R\_BWA01A00 and VAC-L27R\_BWA02A02). The Buffalo Creek impaired segment begins at an unnamed tributary at the Route 811 crossing in Campbell County to its confluence with the Big Otter River.

The DEQ 2008 Fact Sheets for Category 5 Waters (VADEQ, 2008) state that Buffalo Creek is impaired based on assessments at biological station 4ABWA008.53. The source of impairment is described as related to the surrounding residential land uses with “increasing sedimentation and flashy flows causing erosion and nutrient enrichment.”

#### **2.1.3. Pollutants of Concern**

Pollution from both point and nonpoint sources can lead to a violation of the benthic standard. A violation of this standard is assessed on the basis of measurements of the in-stream benthic macro-invertebrate community. Water bodies having a benthic impairment are not fully supportive of the aquatic life designated use for Virginia’s waters.

## **2.2. Designated Uses and Applicable Water Quality Standards**

### **2.2.1. Designation of Uses (9 VAC 25-260-10)**

“A. All state waters are designated for the following uses: recreational uses (e.g. swimming and boating); the propagation and growth of a balanced indigenous population of aquatic life, including game fish, which might reasonably be expected to inhabit them; wildlife; and the production of edible and marketable natural resources (e.g., fish and shellfish).” SWCB, 2010.

### **2.2.2. General Standard (9 VAC 25-260-20)**

The general standard for a water body in Virginia is stated as follows:

“A. All state waters, including wetlands, shall be free from substances attributable to sewage, industrial waste, or other waste in concentrations, amounts, or combinations which contravene established standards or interfere directly or indirectly with designated uses of such water or which are inimical or harmful to human, animal, plant, or aquatic life.

Specific substances to be controlled include, but are not limited to: floating debris, oil scum, and other floating materials; toxic substances (including those which bioaccumulate); substances that produce color, tastes, turbidity, odors, or settle to form sludge deposits; and substances which nourish undesirable or nuisance aquatic plant life. Effluents which tend to raise the temperature of the receiving water will also be controlled.”  
SWCB, 2010.

The biological monitoring program in Virginia that is used to evaluate compliance with the above standard is administered by the Virginia Department of Environmental Quality (DEQ). Evaluations of monitoring data from this program focus on the benthic (bottom-dwelling) macro (large enough to see) invertebrates (insects, mollusks, crustaceans, and annelid worms) and are used to determine whether or not a stream segment has a benthic impairment. Changes in water quality generally result in alterations to the quantity and diversity of the benthic organisms that live in streams and other water bodies. Besides being the major intermediate constituent of the aquatic food chain, benthic macro-invertebrates are "living recorders" of past and present water quality conditions. This is due to their relative immobility and their variable resistance to the diverse contaminants that are introduced into streams. The community structure of these organisms provides the basis for the biological analysis of water quality. Both qualitative and semi-quantitative biological monitoring have been conducted by DEQ since the early 1970's. The U.S. Environmental Protection Agency's (USEPA) Rapid Bioassessment Protocol (RBP) II was employed beginning in the fall of 1990 to utilize standardized and repeatable assessment methodology (Barbour et al., 1999). For any single

sample, the RBP II produces water quality ratings of “non-impaired,” “slightly impaired,” “moderately impaired,” or “severely impaired.” In Virginia, benthic samples are typically collected and analyzed twice a year in the spring and in the fall.

The RBP II procedure evaluates the benthic macro-invertebrate community by comparing ambient monitoring “network” stations to “reference” sites. A reference site is one that has been determined to be representative of a natural, non-impaired water body. The RBP II evaluation also accounts for the natural variation noted in streams in different eco-regions. One additional product of the RBP II evaluation is a habitat assessment. This is a stand-alone assessment that describes bank condition and other stream and riparian corridor characteristics and serves as a measure of habitat suitability for the benthic community.

Beginning in 2006, DEQ modified their bioassessment procedures. While the RBP II protocols were still followed for individual metrics, a new index, the Virginia Stream Condition Index (VSCI), was developed based on comparison of observed data to a set of reference conditions, rather than with data from a reference station. The new index was also calculated for all previous samples in order to better assess trends over time.

Determination of the degree of support for the aquatic life designated use is based on biological monitoring data and the best professional judgment of the regional biologist, relying primarily on the most recent data collected during the current 5-year assessment period. In Virginia, any stream segment with a benthic score less than the impairment threshold is placed on the state’s 303(d) list of impaired streams (VADEQ, 2012).

## **Chapter 3: WATERSHED CHARACTERIZATION**

### **3.1. Water Resources**

The Little Otter River watershed is part of the Roanoke River basin and comprises state hydrologic unit L26 (National Watershed Boundary Dataset watersheds RU53 and RU54). The Little Otter River watershed contains the City of Bedford, Virginia, is intersected by US Route 460 and Virginia Route 43, and lies entirely within Bedford County. The Little Otter River watershed is 43,914 acres in size. The main land use category in the watershed is hay and pasture, which comprises approximately 48% of the watershed, followed by 36% forest, 15% residential or developed land uses, and a very minor 1% in cropland. The Upper Little Otter River flows east southeast to its confluence with Johns Creek, which is the beginning of the Lower Little Otter River. Wells Creek flows east and confluences with Machine Creek, which continues its path in an eastern direction until it flows into the Lower Little Otter River. At that point the Lower Little Otter River flows east until it discharges into the Big Otter River. The Big Otter River is a tributary of the Roanoke River, which flows into the Albemarle Sound.

The Buffalo Creek watershed is part of the Roanoke River basin and comprises part of state hydrologic unit L27 (National Watershed Boundary Dataset RU56). Buffalo Creek is located southwest of Lynchburg on US Route 460 and US Route 221 in both Bedford and Campbell counties. The Buffalo Creek watershed is 15,808 acres in size. The main land use category in the watershed is forest, which comprises approximately 51% of the watershed, followed by 28% pasture, 21% residential or developed land uses, and a very minor 0.4% in cropland. Buffalo Creek flows south southwest, with part of its flow intercepted by Timber Lake above the impaired segment, and discharges into the Big Otter River. The Big Otter River is a tributary of the Roanoke River Basin, which flows into the Albemarle Sound.

### **3.2. Eco-region**

Both of the Little Otter River and Buffalo Creek watersheds are located entirely within the Northern Inner Piedmont (45e) sub-division of the Piedmont (45) ecoregion. Ecoregion 45e is a dissected upland composed of hills, irregular plains, and isolated ridges and mountains. General elevations become higher towards the western

boundary and to the south the Roanoke River where the land rises to become a broad, hilly upland. Ecoregion 45e is characteristically underlain by highly deformed and deeply weathered Cambrian and Proterozoic feldspathic gneiss, schist, and melange. Streams have silt, sand, gravel, and rubble bottoms materials and bedrock is only occasionally exposed. Differences in stream gradient considerably affect fish habitat in the Piedmont. Loblolly - shortleaf pine forests are common (USEPA, 2002).

### **3.3. Soils and Geology**

The Little Otter River watershed is comprised of a diversity of soils with its dominant soil, Cecil fine sandy loam, comprising 34.6% of the watershed. The next two most abundant soil types are Madison sandy clay loam and Hayesville loam at 23.8% and 14.3%, respectively. The Cecil series (fine, kaolinitic, thermic Typic Kanhapludults) consists of very deep, well drained moderately permeable soils on ridges and side slopes of the Piedmont uplands. They are deep to saprolite and very deep to bedrock. They formed in residuum weathered from felsic, igneous and high-grade metamorphic rocks of the Piedmont uplands. The Madison series (fine, kaolinitic, thermic Typic Kanhapludults) consists of well drained, moderately permeable soils that formed in residuum weathered from felsic or intermediate, high-grade metamorphic or igneous rocks high in mica content. They are very deep to bedrock and moderately deep to saprolite. They are on gently sloping to steep uplands in the Piedmont. The Hayesville series (fine, kaolinitic, mesic Typic Kanhapludults) consists of very deep, well drained soils on gently sloping to very steep ridges and side slopes of the Southern Appalachian Mountains. They most commonly formed in residuum weathered from igneous and high-grade metamorphic rocks such as granite, granodiorite, mica gneiss and schist; but in some places formed from thickly-bedded metagraywacke and metasandstone. On steeper slopes the upper part of some pedons may have some colluvial influence (USDA-NRCS, 2012).

The Buffalo Creek watershed is comprised of a diversity of soils with its dominant soil also being Cecil fine sandy loam, which comprising 28.2% of the watershed. The next two most abundant soil types are Cullen loam and Tatum loam at 11.4% and 11.3%, respectively. The Cecil series is described above for the Little Otter River. The Cullen series (very-fine, kaolinitic, thermic Typic Hapludults) are very deep and well

drained with moderate permeability. They formed in residuum from mixed mafic and felsic crystalline rocks. These soils are on upland ridgetops and side slopes of the Piedmont Plateau. The Tatum series (fine, mixed, semiactive, thermic Typic Hapludults) consists of deep, well-drained, moderately permeable soils. They formed in residuum weathered from fine-grained metamorphic rocks (USDA-NRCS, 2012).

### **3.4. Climate**

Climate data for the Little Otter River watershed was based on meteorological observations made by the Bedford National Climatic Data Center station (440551) located within Bedford City, Virginia and on the upstream boundary of the Johns Creek and the Upper Little Otter River watersheds. Average annual precipitation at this station is 45.08 inches; while the average annual daily temperature is 56.1°F. The highest average daily temperature of 75.8°F occurs in August while the lowest average daily temperature of 35.7°F occurs in January, as obtained from the 1981-2010 climate normals (NCDC-NOAA, 2012).

Climate data for the Buffalo Creek watershed was based on meteorological observations made by the Lynchburg #2 National Climatic Data Center station (445120) located within Lynchburg City, Virginia approximately 5.0 miles north northeast of Timber Lake and approximately 11.4 miles north northeast from the Buffalo Creek outlet into Big Otter River. Average annual precipitation at this station is 41.48 inches; while the average annual daily temperature is 54.7°F. The highest average daily temperature of 84.4°F occurs in July while the lowest average daily temperature of 23.6°F occurs in January, as obtained from the 1981-2010 climate normals (NCDC-NOAA, 2012).

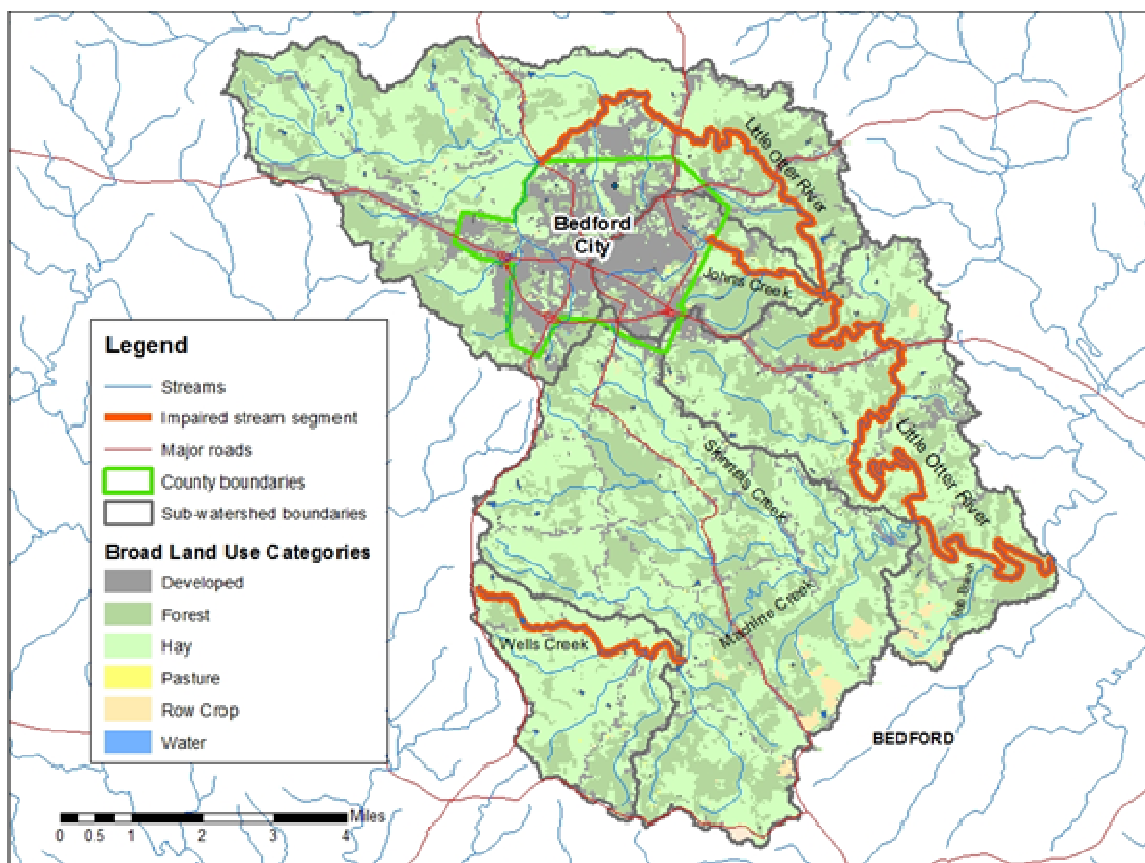

### **3.5. Land Use**

Land use categories for the Little Otter River and Buffalo Creek watersheds were derived from the 2009 cropland data layer developed by the USDA National Agricultural Statistics Service (NASS, 2009). The NASS data are available online and were developed from USDA National Resources Inventory data in agricultural areas and supplemented with 2006 National Land Classification Data (NLCD) in non-agricultural areas. The Little Otter River watershed is 43,913.9 acres in size. The main land use

category in the watershed is pasture/hay (47.5% of the watershed), followed by forest (36.5%), 14.9% developed, and the remainder in cropland (1%). The distribution of land use acreages in the watershed is given in Table 3-1, and shown in Figure 3-1.

**Table 3-1. NASS Land Use Summary in Little Otter River Watersheds (acres)**

NASS Land Use Categories	Johns Creek	Upper Little Otter River	Wells Creek	Lower Little Otter River	LOR Total
Corn	11.62	9.30	3.10	241.00	265.02

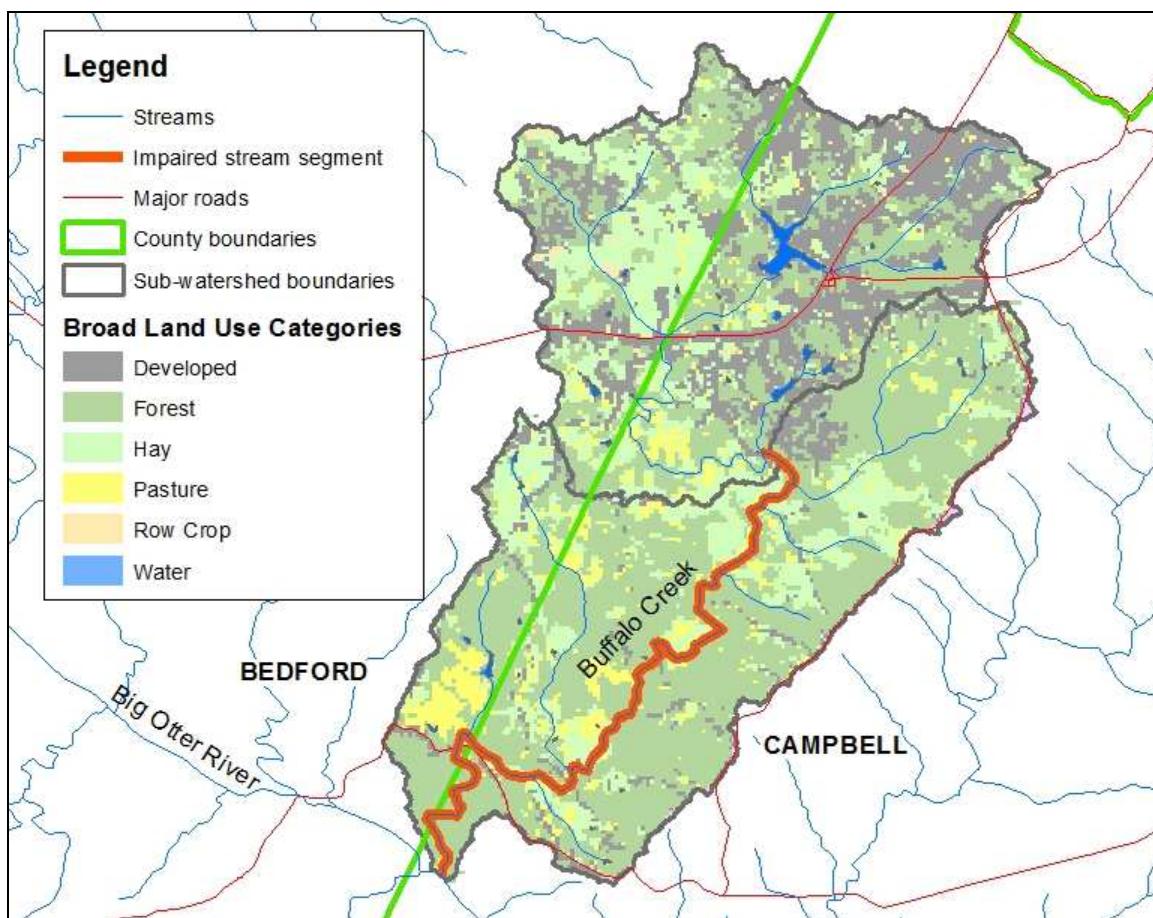

**Figure 3-1. NASS Generalized Land Use in Little Otter River Watersheds**

The Buffalo Creek watershed is 15,808.1 acres in size. The main land use categories in the watershed are forest (50.6% of the watershed), pasture/hay (27.7%), and residential or developed (20.7%) land uses. The remaining less than 1% is in cropland. The distribution of land use acreages in the watershed is given in Table 3-2, and shown in Figure 3-2.

### **3.6. Biological Monitoring Data – Benthic Macro-invertebrates**

Biological monitoring consisted of sampling the benthic macro-invertebrate community along with corresponding habitat assessments. The data for the bioassessments in Little Otter River and Buffalo Creek were based on DEQ biological monitoring at one or more DEQ monitoring sites in each watershed. The locations of the DEQ biological and ambient monitoring stations in the Little Otter River and Buffalo Creek watersheds are shown in Figure 3-3. Monitoring station 4ABWA008.57 was moved to mile marker 8.53 in 2010.

**Figure 3-3. Locations of DEQ Monitoring Stations in the Little Otter River and Buffalo Creek Watersheds**

Biological samples were collected from the best available habitat using riffle or multi-habitat methods. The samples were then preserved and sub-sorted, and then the organisms were identified to the family and/or genus taxonomic level. A full listing of the benthic macro-invertebrate taxa inventory or distribution within each biological sample is given for four Little Otter River TMDL sub-watersheds in Table through Table , and for Buffalo Creek in Table and Table 3-12.

In 2006, DEQ upgraded its biomonitoring and biological assessment methods to those currently recommended by USEPA Region 3 for the mid-Atlantic region. As part of this effort, a study was performed to assist the agency in moving from a paired-network/reference site approach based on the RBP II to a regional reference condition approach, and has led to the development of the Virginia Stream Condition Index (VSCI) for Virginia's non-coastal areas (Tetra Tech, 2003). This multi-metric index is based on 8 biomonitoring metrics, with a scoring range of 0-100, that include some different metrics than those used previously in the RBP II, but are based on the same taxa inventory. A maximum score of 100 represents the best benthic community sites. The

current criteria define “non-impaired” sites as those with a VSCI of 60 or above, and “impaired” sites as those with a score below 60 (VADEQ, 2006).

#### Upper Little Otter River

The biological summaries for the Upper Little Otter River are in Table , Table , and Figure , including a trend line for the single station. The dominant family of benthic macro-invertebrates is the pollution-tolerant Hydropsychidae (net-spinner caddisflies) combined with second dominant family typically being more pollution-sensitive, indicative of better water quality. Individual VSCI metric scores are on a scale of 0-100, with 100 being the best possible score. The primary biological effects are identified as those metrics scoring in the lowest 20th percentile. The primary biological effects in the Upper Little Otter River, indicative of its relatively minor impairment, are the occasional low scores for the scraper functional group and for the sensitive members of the Plecoptera (stoneflies) and Tricoptera (case maker caddisflies) families.

### Johns Creek

The biological summaries for Johns Creek are in Table , Table , and Figure , including a trend line for the single station. The dominant families of benthic macro-invertebrates are the pollutant-tolerant Chironomidae and Hydropsychidae, with occasional dominance by one of the more pollutant-sensitive families. Johns Creek is consistently impaired, but has shown gradual improvement. Individual VSCI metric scores are on a scale of 0-100, with 100 being the best possible score. The primary biological effects are identified as those metrics scoring in the lowest 20th percentile. The primary biological effects in Johns Creek, which parallel its gradual improvement over time, are the scores for the scraper functional group and for the sensitive members of the Plecoptera and Tricoptera families.

Wells Creek

The biological summaries for Wells Creek are in Table , Table , and Figure . The dominant family of benthic macro-invertebrates is the pollutant-tolerant Chironomidae and occasionally, the slightly more sensitive Heptageniidae (mayflies). Individual VSCI metric scores are on a scale of 0-100, with 100 being the best possible score. The primary biological effects are identified as those metrics scoring in the lowest 20th percentile. The primary biological effects in Wells Creek have been the occasional low scores for the scraper functional group and for the sensitive members of the Plecoptera and Tricoptera families. All spring samples have shown impairment, while all fall samples rated as “non-impaired”.

**Lower Little Otter River**

The biological summaries for the Lower Little Otter River are in Table , Table , and Figure , including a trend line for the upstream station. The dominant families of benthic macro-invertebrates are the pollution-tolerant Chironomidae (midges) and Hydropsychidae. Individual VSCI metric scores are on a scale of 0-100, with 100 being the best possible score. The primary biological effects are identified as those metrics scoring in the lowest 20th percentile. The primary biological effects in the Lower Little Otter River, indicative of its relatively minor impairment, are the occasional low scores for the scraper functional group and for the sensitive members of the Plecoptera and Tricoptera families.

## Buffalo Creek

The biological summaries for Buffalo Creek are in Table , Table and Figure , including a trend line for the upstream station. The dominant families of benthic macro-invertebrates at the Buffalo Creek site included a balance of mildly pollution-tolerant and mildly pollution-sensitive taxa. Individual VSCI metric scores are on a scale of 0-100, with 100 being the best possible score. The primary biological effects are identified as those metrics scoring in the lowest 20th percentile. The primary biological effects in Buffalo Creek, indicative of its relatively minor impairment, are the occasional low scores for the scraper functional group and the sensitive members of the Plecoptera and Tricoptera families.

### **3.7. Biological Monitoring Data – Habitat**

A qualitative analysis of various habitat parameters was conducted in conjunction with each benthic macro-invertebrate sampling event. Habitat data collected as part of the biological monitoring were obtained from DEQ through the EDAS database. For each evaluation, ten metrics are scored on a 0-20 basis using EPA rapid bioassessment protocols (Barbour et al., 1999), with scores of 0-5 rated as “poor”; scores of 6-10 as “marginal”; scores of 11-15 as “sub-optimal”; and scores of 16-20 rated as “optimal”, with minor variations for those metrics scored separately for each stream bank. The maximum 10-metric total habitat score is 200; scores <120 are considered sub-optimal, and those >150 as optimal. The 10 metrics evaluated vary based on whether the best available habitat was dominated by riffle or multi-habitat (snags, leaf packs). The former is considered “high gradient” and the latter “low gradient.”

The habitat assessment data for the Upper Little Otter River are shown in Table . Scores for all of the “sediment deposition” metric and for all but 2 of the “bank stability” metric were rated as “poor”. All of the samples, except the first one and the second to last are rated as “sub-optimal”.

**Table 3-13. Habitat Metric Scores for Upper Little Otter River (LOR)**

- Marginal or Poor habitat metric rating.

<sup>1</sup> Metric is the sum of scores for both the left and right banks.

<sup>2</sup> Total Habitat Score: **optimal** > 150; **suboptimal** < 120.

\* Substitute metrics used under "Low Gradient" conditions.

The habitat assessment data for Johns Creek are shown in Table . The “bank stability” and “sediment deposition” metrics have consistently received “poor” scores, as has “vegetative protection” for all but the first sample. All of the visits to Johns Creek resulted in “sub-optimal” Total Habitat Scores.

<b>10-Metric Total Habitat Score<sup>2</sup></b>	<b>134</b>	<b>115</b>	<b>117</b>	<b>125</b>	<b>118</b>

 - Marginal or Poor habitat metric rating.

<sup>1</sup> Metric is the sum of scores for both the left and right banks.

<sup>2</sup> Total Habitat Score: **optimal** > 150; **suboptimal** < 120.

The habitat assessment data for the Lower Little Otter River are shown in Table . While none of the samples have rated “poor” for all habitat metrics, many of the samples have received “poor” scores for the “bank stability”, “vegetative protection”, and “sediment deposition” metrics. The habitat appears to be slightly better in the downstream section of Lower Little Otter River than upstream.

**Table 3-16. Habitat Metric Scores for Lower Little Otter River (LOR)**

- Marginal or Poor habitat metric rating.

<sup>1</sup> Metric is the sum of scores for both the left and right banks.

<sup>2</sup> Total Habitat Score: optimal > 150; suboptimal < 120.

\* Substitute metrics used under "Low Gradient" conditions.

The habitat assessment data for Buffalo Creek are shown in Table . Habitat data collected as part of the biological monitoring were also obtained from DEQ through the EDAS database. The “riparian vegetative zone width”, “bank stability”, and “embeddedness” metrics have occasionally received “poor” scores. The total habitat scores are better at the downstream station (4ABWA002.00) and appear to be quite variable over time at the upstream station (4ABWA008.53). The 10-metric total possible score is 200; scores <120 are considered sub-optimal, and those >150 as optimal.

## 3.8. Water Quality Data

### 3.8.1. DEQ Ambient Monitoring Data

#### Little Otter River

Ambient bi-monthly monitoring has been performed on the Little Otter River impaired segments at various stations and for varying periods at each station since 1992. Field physical parameters include temperature, DO, pH, and conductivity. Chemical parameters include: nitrogen (N) species - ammonia-N, nitrate-N, nitrite-N, TKN, and total N; total phosphorus (P); total filterable residue (suspended solids); chloride; and bacteria fecal coliform and Escherichia coli. Average nutrient concentrations at the various stations are summarized in Table , along with two calculated ratios to assist in assessing nutrient influences in these watersheds.

**Table 3-18. Nutrient Concentration Averages and Ratios**

Station ID	Beg. Date	End Date	NITROGEN, TOTAL (mg/L)		NITRATE NITROGEN (mg/L)		NITROGEN, KJELDAHL TOTAL (mg/L)		PHOSPHORUS, TOTAL (mg/L)		TN:TP Ratio	TKN:TN Ratio

- Indicates elevated values.

Plots of monthly ambient water quality monitoring parameters are shown in the following figures for available data from January 1994 through April 2012. Plots are grouped by parameter for stations on the Upper LOR (Little Otter River), the Lower LOR stations, Johns Creek, and Wells Creek sub-watersheds. Where few or no samples were available at monitoring stations in a given sub-watershed, a summary of the data are given instead. Data for Machine Creek (MCR) are included in the analysis as Machine Creek is the tributary link between Wells Creek and the Lower LOR.

The parameter shown in the plots include: temperature (Figures 3-9 to 3-12); dissolved oxygen (Figures 3-13 to 3-16); pH (Figures 3-17 to 3-20); specific conductivity (Figures 3-21 to 3-24); nitrogen (Upper LOR: Figures 3-25 to 3-26; Lower LOR: Figures 3-27 to 3-28); total phosphorus (Upper LOR: Figures 3-29; Lower LOR: Figures 3-30); total filterable residue, also called suspended solids (Upper LOR: Figures 3-31; Lower LOR: Figures 3-32); chloride (Upper LOR: Figures 3-33; Lower LOR: Figures 3-34), fecal coliform (Upper LOR: Figures 3-35; Lower LOR: Figures 3-36), and *Escherichia coli* (Upper LOR: Figures 3-37; Lower LOR: Figures 3-38).

Where applicable, minimum and/or maximum water quality standards, minimum detection limits (MDL), and sample analysis caps are indicated on the plots. All stream segments within these watersheds are Class III Nontidal Waters, Coastal and Piedmont Zones (SWCB, 2011).

  - Johns Creek: 1 sample at 80 cfu/100 mL.
  - Wells Creek: 8 samples, averaging 816 cfu/100 mL.

**Buffalo Creek**

Ambient bi-monthly monitoring has been performed on the Buffalo Creek impaired segment at the 4ABWA002.00 ambient station since July 2003, once at the 4ABWA007.87 station in April 2000, and once at station 4ABWA008.53 in April 2003.

Nutrient data in Buffalo Creek are summarized in Table to assist in assessing nutrient influences in these watersheds.

**Table 3-19. Nutrient Concentration Averages and Ratios**

Station	Period	TN		NO2+NO3-N		TKN		TP		TN:TP Ratio	TKN:TN Ratio
		No.	Ave.	No.	Ave.	No.	Ave.	No.	Ave.		
4ABWA002.00	2003-2005	12	0.77	0		0		12	0.039	19.74	
	2007-2009	18	0.67	0		0		18	0.028	23.57	
	2010-2012	13	0.80	0		0		14	0.036	21.96	
4ABWA007.87	2000	1	0.84	1	0.38	1	0.4	1	0.040	21.00	0.48
4ABWA008.53	2003	1	0.82	1	0.35	1	0.3	1	0.010	82.00	0.37

Where applicable, minimum and/or maximum water quality standards, minimum detection limits (MDL), and sample analysis caps are indicated on the plots. All stream segments within these watersheds are Class III Nontidal Waters, Coastal and Piedmont Zones (SWCB, 2011).

Plots of monthly ambient water quality monitoring sample data for the ambient monitoring station in Buffalo Creek are shown in Figure 3-39 through Figure 3-46.

Field physical parameters include temperature, pH, DO, and conductivity. Chemical parameters include: total N; total P; ammonia (only 1 of 18 samples above the minimum detection limit - data not shown); total nonfilterable residue (suspended solids); and bacteria (fecal coliform [only 6 samples - data not shown] and *Escherichia coli*).

**Figure 3-46. Non-filterable residue**

Summaries of violations of water quality standards based on DEQ monitoring are included in the state's biennial 305(b)/303(d) Combined Report, as shown in Table .

In the Little Otter River and tributaries, in addition to the biological monitoring reported previously, the bacteria exceedences being addressed by the Big Otter River IP, and the PCB impairment in the Little Otter River being addressed in the Roanoke (Staunton) River PCB TMDL, the following water quality standards exceedences have been reported in these reports:

- Total Phosphorus: multiple exceedences at various upstream and downstream stations on the main channel of the Little Otter River, all reported prior to 2004.
- Metals in Fish Tissue: two violations on the Little Otter River at different stations prior to 2002.
- Metals and Organics in Benthic Organisms: 1 violation of organics has occurred at station 4ALOR007.94 during each assessment since 2002, leading to it being assessed as impaired for organics beginning in 2006. Beginning in 2008, the same station has been assessed as impaired for metals in benthics.

In Buffalo Creek, the following water quality exceedences were reported:

- **Bacteria:** a bacterial impairment at station 4ABWA002.00 beginning in the 2006 report.
- **pH:** Two minor pH violations were reported around Timber Lake by citizen monitoring, once in 2006 and once in 2007.

**Table 3-20. Summary of 305(b)/303(d) Integrated Report Monitored Exceedences**

### **3.8.2. DEQ Stream Tests for Metals and Organic Compounds**

#### **Little Otter River**

Twenty-six sediment samples have been collected over time in the encompassing Little Otter River watershed and analyzed by DEQ for a standard suite of metals; 1 in Johns Creek, 14 in Lower Little Otter River, 10 in the Upper Little Otter River, and 1 in Wells Creek.

Only one of the tested substances, zinc, exceeded any established consensus-based probable effects concentration (PEC) screening criteria. That sample was taken in 1993 and all subsequent samples showed more typical concentrations for that site.

Most of the metals were not detected above their respective minimum detection limit (MDL), as shown in Table . In addition to the metal parameters listed in the table, up to 24 other metal and/or organic compounds in each sample were analyzed with no detects in any sample.

**Table 3-21. DEQ Channel Bottom Sediment Monitoring and Screening Criteria for Metals**

Station ID	Collection Date	Metals Measured in Stream Channel Bottom Deposits

U = parameter analyzed, but not detected.

QQ = Analyte detected above the MDL but below the method quantification limit.

TEC = Threshold effects concentration; PEC = Probable effects concentration.

In addition to the parameters listed above, up to 24 parameters in each sample were analyzed with no detects in any sample; however, not all parameters were analyzed in each sample.

Seven samples, taken on the same day as one of the sediment metals samples, were analyzed for dissolved metals. These results are shown in Table . Only one sample exceeded any of the applicable aquatic life, human health, or EPA nationally recommended freshwater criteria (a historical Upper Little Otter River sample in July 1993 with the exceeding parameter being zinc). Additionally, none of the samples that were analyzed detected the presence of cadmium, lead, thallium, or silver.

- Sample concentrations below minimum limits of detection.

- Sample concentration exceeding one or more criteria.

CMC = criteria maximum concentration (acute criterion)

CCC = criterion continuous concentration (chronic criterion)

QQ = Analyte detected above the MDL but below the method quantification limit.

Heavy metals such as mercury, chromium, cadmium, arsenic and lead in streams and rivers can damage aquatic insects at low concentrations. The metals tend to accumulate in the gills and muscles of aquatic organisms. Dissolved metals have been identified as important predictors of stream health. In the context of water quality criteria, dissolved metals are typically treated independently; however there is strong evidence that metals have a cumulative effect (Clements et al., 2000). The Cumulative Criterion Units (CCU) metals index accounts for this additive effect by standardizing each dissolved metal's concentration. The metals are summed together and the result is the CCU Metals Index score. When the CCU Metals Index is above 2, the cumulative effect is considered likely to harm aquatic life (Clements et al., 2000). The average CCU score for the sets of dissolved metals samples in Table was 0.18, ranging between 0.09 and 0.22, well below the threshold of concern.

### Buffalo Creek

One sediment sample was collected for Buffalo Creek watershed and analyzed by DEQ for a standard suite of metals. None of the tested substances exceeded any

established consensus-based probable effects concentration (PEC) screening criteria, and most of the metals were not detected above their respective minimum detection limit (MDL), as shown in Table .

- Minimum detection limit.

DEQ uses its Probabilistic Monitoring Program to pilot innovative sampling techniques. During 2003, semi-permeable membrane devices (SPMD), or “virtual fish” were deployed for a minimum of 30 days at 41 randomly located stations across the state. SPMDs mimic the uptake of organic compounds into fish tissue by utilizing a synthetic fish oil inside a porous membrane. Station 4ABWA008.53 was one of the 41 randomly selected stations for SPMD deployment. The results of the analysis of the membrane are shown in Table . Note that the measured SPMD units and the WQS units are not directly comparable. The WQS are cited to show a relative magnitude of the various compounds, and the comments on the far right indicate the relative magnitude of the SPMD measured values relative to other SPMD measurements made in the state.

**Table 3-25. Organic Compounds Detected with the Semi-Permeable Membrane Device (SPMD) at Station 4ABWA008.53**

Criteria exceeded by one or both samples.

### 3.8.3. DEQ - Other Relevant Monitoring or Reports

#### Relative Bed Stability (RBS) Analysis

A Log Relative Bank Stability (LRBS) test is a type of siltation index. An LRBS score of negative one (-1) indicates that sediments ten times larger than the median are moving at bankfull, with a medium probability of impairment from sediment. A high percentage of fine sediment in streams would directly contribute to embeddedness, the filling of the interstitial spaces in the channel bottom. LRBS scores < -1 are considered sub-optimal, while scores > -0.5 are considered optimal. All four Little Otter River sub-watersheds have a relatively high percentage of mean embeddedness according to this test, although the percent of fine material varies considerably among them. The LRBS indicates sediment as a major source in the Upper Little Otter River (4ALOR014.75) and Wells Creek, while Johns Creek is less than optimal, and the Lower Little Otter River (4ALOR007.20) scoring in the optimal range, as shown in Table . The low LRBS score at the upstream site on the main channel in the Little Otter River is indicative of highly modified channels, while the higher score at the downstream site may indicate recovery and a fairly healthy reduced loading from fines. The low LRBS score at the upstream Buffalo Creek site (4ABWA008.53) is indicative of highly modified channels, while the downstream site, even though it also has a low LRBS score, shows recovery with a reduced degree of embeddedness and a reduced loading from fines.

**Table 3-26. RBS Analysis Results**

StationID	Date	Percent Sand	Percent Fines	Mean Embeddedness (%)	LRBS*
4AJHN000.01	10/16/08	50.5%	6.8%	55.4	-0.703
4ALOR007.20	10/23/07	64.4%	0.0%	56.2	-0.249
4ALOR014.75	10/16/08	75.0%	11.0%	58.0	-1.207
4AWEL000.59	09/19/05	37.1%	20.0%	54.2	-1.124
4ABWA002.00	07/09/12	2.9%	0.0%	36.0	0.924
4ABWA008.53	07/09/12	4.8%	50.5%	55.1	-0.844

\* LRBS > -0.5 indicates a normal sediment load;  
 LRBS < -1.0 indicates excessive sediment load.

### 3.8.4. Permitted Point Sources

There are no general discharge permits for single-family homes in any of the Little Otter River or Buffalo Creek watersheds.

There is one municipal separate stormwater sewer system (MS4) permit for the roads and facilities of the Virginia Department of Transportation (VA040115) in the upper Buffalo Creek watershed, extending from the Lynchburg urbanized area.

There are two VPDES permits, one general permit, 6 industrial stormwater general permits (ISWGP), and one integrated discharge permit for a concrete facility in the Little Otter River watersheds, while there is only one ISWGP in Buffalo Creek, as shown in Table .

**Table 3-27. Permitted Discharges**

Facility Name	Permit No	Permit Type	Water Body	Receiving Stream
Bedford City - Wastewater Treatment Plant	VA0022390	VPDES	VAW-L26R	Little Otter River

The two VPDES and one General Permit holders above are required to perform monthly monitoring and to meet average and/or maximum, concentration and/or quantity pollutant limits. Table provides a summary of the permitted pollutants in each of these permits, their permitted limits, and a summary of their discharge monitoring report (DMR) discharges.

- Of the two permit exceedences noted for the Bedford City WWTP, both were minor with the Biological Oxygen Demand (BOD) exceedence occurring in 2007, and the zinc exceedence occurring in 2002.
- Of the permit exceedences listed for Body Camp Elementary:
  - Flow: 11/117 exceedences; 7 between Jul-05 and Nov-07; 5 since Jun-11.

- BOD5: the average concentration limit has been exceeded 6 times; once in 2001 and the rest since May-10; the maximum concentration limit has been exceeded three times all since May-10; the average daily quantity limit has been exceeded 3 times all since May-10; and maximum quantity limit has been exceeded once in Jul-11.
- TSS: 2 minor exceedences in 2001.
- Ammonia: 36/89 measurements exceed the concentration average, but only one sample has exceeded since Oct-09.

ND = substance not detected.

Between January 2008 and June 2012, there have been 29 land disturbing (construction stormwater) permits issued in the encompassing Little Otter River watershed representing a total disturbed acreage of 35.60 acres. Of those permits, 6 are current, comprising a total of 3.25 acres. Additional local construction permits for areas < 5 acres in size may also exist for single family construction and other small-scale construction.

During the same time period, there have been 10 land disturbing (construction stormwater) permits issued in the Buffalo Creek watershed representing a total disturbed acreage of 17.04 acres. Of those permits, 4 are current, comprising a total of 8.34 acres. Since 2010, Campbell County reports local construction permits in their portion of Buffalo Creek totaling 35.13 acres of disturbed land, of which 23.3 acres were for single family construction and the rest for commercial construction.

### **3.8.5. VAHWQP Household Drinking Water Analyses**

The Virginia Household Water Quality Program (VAHWQP) conducted Drinking Water clinics in Appomattox and Campbell counties in May-June 2009, and in Bedford County in June-July 2009, where homeowners brought in well or spring water samples and/or tap water samples for water quality testing and analysis, shown in Table . Since most of these samples are typically collected from household taps and, therefore, have been subject to treatment by a household water treatment system, they are not generally representative of the broader background groundwater quality in the area.

Some of the constituents, such as nitrate, however, are not typically treated by a household water treatment system, and may be representative of groundwater.

**Table 3-30. VAHWQP County Drinking Water Clinic Results**

Test	Standard	Appomattox and Campbell Counties, 2009 (n=30); Benham et al., 2010a.			Bedford County, 2009 (n=34); Benham et al., 2010b.

### **3.8.6. Big Otter River Bacteria TMDL and Implementation Plan**

The bacteria impairments in Big Otter River and its tributaries, which include all of the Little Otter River sub-watersheds, were previously addressed by the TMDL developed in 2000 (Mostaghimi et al., 2000) and the Implementation Plan in 2006 (VT-BSE, 2006). Any reductions required by this TMDL developed for the benthic impairment will be coordinated with those called for by the bacteria TMDL and IP.

### **3.8.7. Recent Implementation of Best Management Practices (BMPs)**

#### Little Otter River

Peaks of Otter SWCD reported implementation of livestock exclusion along 31.9 miles of stream in the Little Otter River watershed. This implementation was funded under a \$319 Grant for the Big Otter River Implementation Plan conducted between July 2006 and June 2011. Of that total, 10.8 miles was along streams in the Upper Little Otter River, 17.8 miles along streams in the Lower Little Otter River, 3.3 miles along Wells Creek, and none along Johns Creek.

In September 2009, the City of Bedford Waste Water Treatment Division received a grant from the Virginia Clean Water Revolving Loan Fund Program, which was administered by DEQ, to install piping and equipment to be able to re-use the effluent, for non-contact use, from the Waste Water plant to Brooks Food Group. This project reduced the amount of potable water used at Brooks Food Group and also reduced the amount of process water used at the Waste Water plant. Construction was completed for this project in May 2010. After completion, the amount of potable water used reduced by 0.5 million gallons per month. In February 2011, the City of Bedford and Anderson & Associates, Inc. received the 2011 Engineering Excellence Honor Award for the Bedford Reclaimed Water Management Project given by ACEC Virginia (Bedford, Virginia Online).

DEQ has reported various actions taken to remediate identified sources of groundwater pollution in the watershed. Through the Bedford County Source Water Protection (SWP) program, an unlined landfill and associated seepage areas were found to be contributing volatile organic compounds (VOCs) to surface waters, and have been fenced off to allow volatilization, photo-degradation, and dilution, and to prevent access by livestock. A second older landfill in Bedford City had also been the source historically of many VOC exceedences of groundwater protection standards, and has been addressed with a seep collection and treatment system (SCTS) which captures seep water and transfers it to the WWTP for treatment. The SCTS captures between 350,000 and 500,000 gallons of seepage per month. Although VOCs are still detected below the landfill in Johns Creek, their concentrations are below groundwater standards (Gilmer, personal communication).

#### Buffalo Creek

Campbell County reported a total of 29 post-construction BMPs installed in the urban areas of its portion of the Buffalo Creek watershed between 2010 and the present, amounting to 5 extended detention ponds, 3 infiltration BMPs, 18 detention ponds, and 3 bio-retention installations.

Virginia Department of Forestry (VDOF) reported approximately 130 logging jobs in the Buffalo Creek watershed between 2009 and the present. Individual jobs varied in size from 1 to 100 acres.

The following BMPs have been reported in DCR's Agricultural Cost-share Database in each county portion:

**Table 3-31. Agricultural BMPs in Bedford County portion of Buffalo Creek Watershed**

BMP Code	BMP Name	Installed Units	Program Year				Grand Total
			2004	2007	2009	2010	
CP-22	Riparian Buffer Rent	Acres	3.9				3.9
CRFR-3	CREP Riparian Forest Buffer Planting	Acres	3.9				3.9
RB-4	Septic Tank System Replacement	Count			3	1	4

### **3.8.8. Lynchburg College Studies on Timber Lake**

Kate Skaggs conducted her senior research thesis on Timber Lake (2006) which provided some baseline water quality data for its contributing watershed. She notes that the original dam for the lake was breached in 1995, with the lake subsequently dredged and the dam rebuilt. In 1999, Timber Lake's watershed was established as a Watershed Improvement District (WID) with the power to tax residents, though that power has not yet been exercised. Three streams are tributary to Timber Lake: Buffalo Creek, Waterlick Creek, and Brown Creek. She noted that all three streams are somewhat impacted by urban development, but currently are in overall good health for urban streams. Timber Lake itself was assessed as being mesotrophic. High phosphorus

levels are currently held in check by large numbers of *Daphnia* zooplankton, preventing excessive algal blooms. She notes, however, that increased nutrient loading from the tributaries due to increased development could rapidly shift that balance.

Data were collected for the Timberlake Homeowners Association (THA) by Lynchburg College over an unspecified period of time. Calculations from spreadsheet data attributed to Ashley Palmer at Lynchburg College from 2010, quantified the net consumption and/or storage of phosphorus within Timber Lake on six monthly samples from June - November, although units could not be verified.

#### **3.8.9. Citizen Monitoring Data from THA**

Monthly ambient water quality data has been collected at 11 points around Timber Lake and its tributary streams by THA from January-July 2006 and from March-September 2007. The THA data have been certified as level III data by DEQ. The location of the monitoring sites are shown in Figure 2-47, while graphs of the 9 physical, chemical and bacteria parameters are presented in Figures 3-48 through 3-56.

A professional lake monitoring service from Mechanicsville was contracted for data collection and analysis in 2012, but the data results are not currently available.

## **Chapter 4: BENTHIC STRESSOR ANALYSIS**

### **4.1. Introduction**

TMDLs must be developed for a specific pollutant. Since a benthic impairment is based on a biological inventory, rather than on a physical or chemical water quality parameter, the pollutant is not explicitly identified in the assessment, as it is with physical and chemical parameters. The process outlined in USEPA's Stressor Identification Guidance Document (USEPA, 2000) was used to identify the critical stressor for each of the impaired stream segments in this study. A list of candidate causes was developed from the listing information, biological data, published literature, and stakeholder input. Chemical and physical monitoring data from DEQ provided additional evidence to support or eliminate the potential candidate causes. Biological metrics and habitat evaluations in aggregate provided the basis for the initial impairment listing, but individual metrics were also used to look for links with specific stressors, where possible. Volunteer monitoring data, land use distribution, Virginia Base Mapping Project (VBMP) aerial imagery, and visual assessment of conditions in and along the stream corridor provided additional information to investigate specific potential stressors. Logical pathways were explored between observed effects in the benthic community, potential stressors, and intermediate steps or interactions that would be consistent in establishing a cause and effect relationship with each candidate cause. The candidate benthic stressors included ammonia, hydrologic modifications, nutrients, organic matter, pH, sediment, TDS/conductivity/sulfates, temperature, and toxics. The details of the stressor analyses are included in the Little Otter River and Buffalo River Stressor Analysis Reports (Yagow et al., 2012a; Yagow et al., 2012b), dated December 6, 2012, and the summaries presented in the following section.

## **4.2. Stressor Analyses Summaries**

The Upper Little Otter River (VAW-L26R\_LOR04A00) stream segment is impaired, but on an overall increasing trend for its aquatic life use, with 2 out of 4 recent individual VSCI sample scores being in the “non-impaired” range. The Upper Little Otter River is impacted by a combination of urban and agricultural land uses. Sediment was selected as the most probable stressor based on the poor stream bank habitat scores and the evidence given by the LRBS analysis indicating excessive sediment contributions from anthropogenic sources.

The Johns Creek (VAW-L26R\_JHN01A00) stream segment was severely impaired for its aquatic life use between 1997 and 2008, but has been gradually improving. Johns Creek is impacted by a combination of urban and agricultural land uses. Sediment was selected as the most probable stressor based on consistently poor habitat sediment metrics.

The Wells Creek (VAW-L26R\_WEL01A02) stream segment shows impairment for its aquatic life use primarily in the spring samples, with the most recent individual VSCI fall sample score being in the “non-impaired” range. Wells Creek is impacted primarily by agricultural land uses. Sediment was selected as the most probable stressor based on the poor habitat sediment scores and the evidence given by the LRBS analysis indicating excessive sediment contributions from anthropogenic sources.

The Lower Little Otter River (VAW-L26R\_LOR01A00, VAW-L26R\_LOR02A00, VAW-L26R\_LOR03A00) stream segments are impaired for their aquatic life use, with the degree of impairment decreasing over time and from upstream to downstream, although the most recent samples have once again shown signs of stress. The Lower Little Otter River is impacted primarily by TP from the WWTP effluent discharge, with sediment coming from a combination of upstream impaired segments, in-stream bank and channel erosion, and land disturbance in the immediate watershed. Although the WWTP is not monitoring for nutrients at this time, it is bracketed by DEQ monitoring stations within a half mile of each other, which show increased nutrient levels at the downstream station with no other plausible source of nutrients. Therefore, the most

probable stressors in this segment are both nutrients and sediment, with nutrients primarily and apparently related to WWTP effluent discharge.

The Buffalo Creek (VAC-L27R\_BWA01A00, VAC-L27R\_BWA02A02) stream segment is impaired for its aquatic life use, primary in the upstream portion of the segment, with some recovery shown in the downstream segment, whose watershed is predominantly forested. Buffalo Creek is impacted by both urban/residential development and agricultural land uses. Sediment was selected as the most probable stressor based on the low upstream LRBS score, livestock with stream access, and the presence of many other land-disturbing activities.

Therefore, sediment TMDLs will be developed to address the benthic impairments in Upper Little Otter River, Johns Creek, Wells Creek, the Lower Little Otter River, and Buffalo Creek.

The aquatic life use impairment in the Lower Little Otter River is heavily influenced by TP discharge from the Bedford City WWTP. Permit limits on TP for the WWTP have been recommended, after analysis of preliminary modeling and in consultation with state and regional DEQ personnel.

In addition to the benthic impairments, these watersheds are part of the larger Big Otter River watershed, which also has a bacteria impairment addressed during a previously developed TMDL (Mostaghimi et al., 2000) and implementation plan (VT-BSE, 2006). Pollutant sources which are being addressed to effect bacteria load reductions in the bacteria TMDL will also effect reductions from the identified benthic impairment stressors - TP and sediment. In particular, the bacteria TMDL calls for reductions of 85% from bacteria loads on cropland and pasture and 30% reduction from livestock with direct stream access. Since the bacteria reductions from cropland and pasture loads relate primarily to livestock manure, they will also reduce TP loads from these sources. The livestock exclusion BMP will further reduce loads of TP and sediment.

## **Chapter 5: SETTING REFERENCE TMDL LOADS**

Since there are no in-stream water quality standards for sediment in Virginia, an alternate method was needed for establishing a reference endpoint that would represent the “non-impaired” condition.

### **5.1. Sediment**

In the past, a reference watershed approach has been used based on a single reference watershed that has similar characteristics as the TMDL watershed, except that it has a healthy benthic community. One problem with this approach can be finding a suitable reference watershed, especially in minimally-impaired and urban watersheds. A second problem with this approach is in identifying the threshold sediment load that is sufficient for attainment of biological integrity, since the load from the reference watershed may be overly conservative.

For the Little Otter River and Buffalo Creek sediment impairments, the procedure used to set TMDL sediment endpoint loads is a modification of the methodology used to address sediment impairments in Maryland’s non-tidal watersheds (MDE, 2006, 2009), hereafter referred to as the “all-forest load multiplier” (AllForX) approach. AllForX is the ratio of modeled sediment loads from the same watershed: the existing condition load divided by the load from an all-forest condition. The AllForX approach was applied locally, using the monitoring stations with impairments and a multiple selection of monitoring stations with healthy biological scores. A regression was developed between the average Virginia Stream Condition Index (VSCI) biological index scores at individual monitoring stations and the corresponding AllForX ratio from their contributing watersheds. The full AllForX methodology is detailed in Appendix F.

#### **5.1.1. Selection of Local Comparison Watersheds**

The selected comparison watersheds were nearby watersheds that have healthy biological communities as measured by the VSCI. Additional criteria used for selection of the comparison watersheds included:

- The same river basin as the impaired stream, preferably

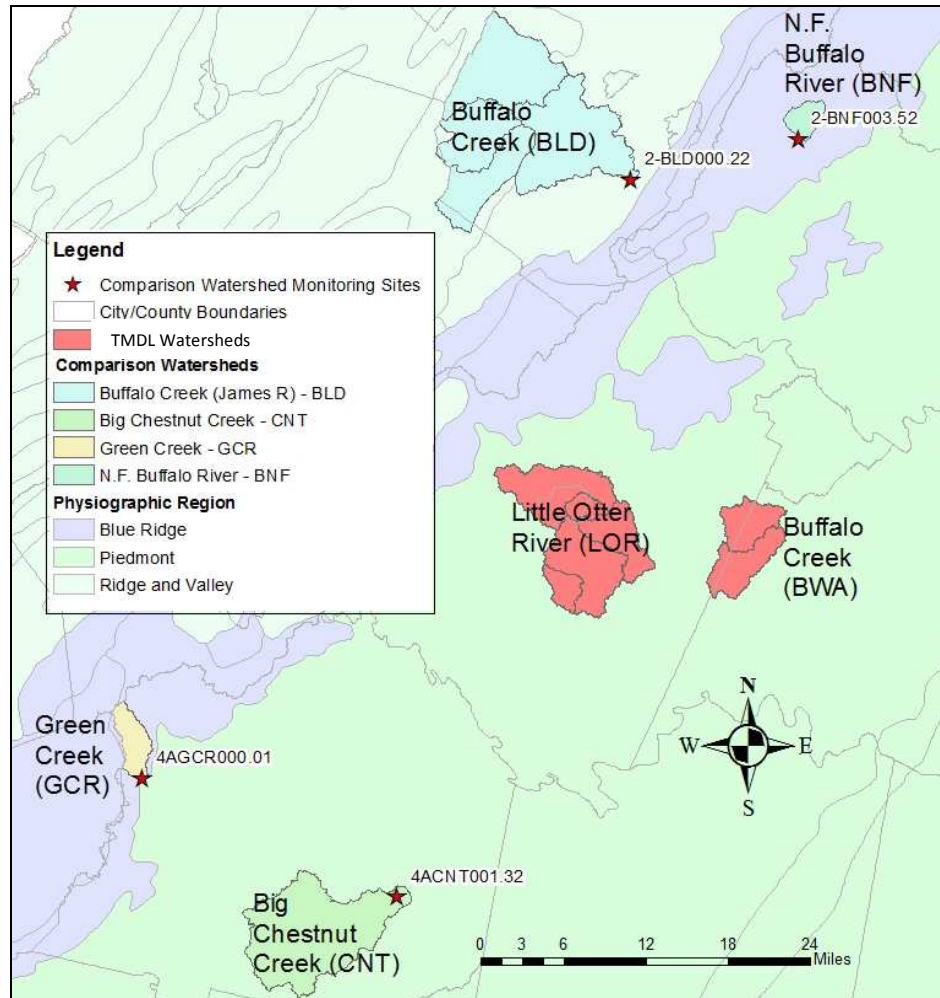

- 1<sup>st</sup> - 3<sup>rd</sup> order streams, preferably
- More than one DEQ biological sample

Four comparison watersheds were identified for application of the AllForX approach with the Little Otter River and Buffalo Creek watersheds. Although not all selected watersheds were in the same major river basin as shown in Table , they were all on the same side of the Appalachian Mountains to prevent major orographic differences. Although two of the selected comparison watersheds were of a larger stream order, their watersheds were not that different in size from the combined Little Otter River sub-watersheds which impact the most downstream impaired segment. While initially it was considered preferable that all comparison watersheds be in the same eco-region as well, the locations of the impaired segments were very close to the eco-region boundaries, so this criterion was relaxed. While not all criteria were met, the proximity of these healthy watersheds to the watersheds draining to the impaired segments was used as the overriding factor in their selection. Table summarizes the various characteristics in support of the selection criteria, while Figure illustrates the proximity of the comparison watersheds to the watersheds contributing to the impaired segments.

**Table 5-1. Summary of Watershed Characteristics**

DEQ Station ID	Stream Name	River Basin	Stream Order	Level III Eco-region	Modeling Watershed	Watershed Area (acres)	No. of Biological Samples	Average VSCI
Buffalo Creek Stations								
4ABWA002.00	Lower Buffalo Creek	Roanoke River	2	Piedmont (45)	BWA1	8,600	2	58.4

4ACNT001.32	Big Chestnut Creek	Roanoke River	4	Piedmont (45)	CNT	39,233	5	75.2
4AGCR000.01	Green Creek	Roanoke River	1	Piedmont (45)	GCR	5,894	13	68.0

**Figure 5-1. Location of TMDL and Comparison Watersheds**

Although the TMDL was developed for sediment, attainment of a healthy benthic community will ultimately be based on biological monitoring of the benthic macro-invertebrate community, in accordance with established DEQ protocols. If a future review should find that the reductions called for in these TMDLs based on current modeling are found to be insufficiently protective of local water quality, then revision(s) will be made as necessary to provide reasonable assurance that water quality goals will be achieved.

## **5.2. Total Phosphorus**

A partial review was conducted of previous TP TMDL endpoints used in Virginia and neighboring states, Virginia DEQ probabilistic monitoring screening level optimal

and sub-optimal thresholds, and various percentile concentrations from both an upstream watershed with a minor benthic impairment (related to sediment) and a non-impaired neighboring watershed, as shown in Table 5-2.

**Table 5-2. Potential TP Endpoints Considered for the Lower Little Otter River**

<b>Studies and Statistics</b>	<b>TP (mg/L)</b>
Upstream Station 4ALOR014.75, 2007-2012 (n=53); minor benthic impairment due to sediment	
Median	0.055
Mean	0.072
75th percentile	0.080
90th percentile	0.120
Virginia DEQ Probabilistic Monitoring Screening Levels (n=471)	
Optimal	< 0.02 or 0.05
Sub-optimal	> 0.05 or 0.10
100% Probability of Impairment	0.210
EPA Recommendations for Eco-Region IX	
Piedmont (45)	0.030
All Physiographic Regions (45,64,65)	0.037
Big Otter River Station 4ABOR033.22 Samples (n = 3); non-impaired	
Average	0.043
90th percentile	0.070
Nutrient TMDL Endpoints	
Sheeder and Evans, 2004 (PA)	0.070
Pitts Creek (VA) - EPA recommended	0.030
Parker Creek (VA)	0.100
Jackson River (VA) - periphyton/ortho-P	0.038
TP equivalent	0.063

The TP endpoint was set at an average annual in-stream concentration of 0.070 mg/L, based on the 90<sup>th</sup> percentile concentration at the Big Otter River station 4ABOR033.22. This endpoint is considered to be protective of the benthic community, as it was a value in the mid-range of TP endpoints used previously and came from a neighboring non-impaired reference watershed.

## **Chapter 6: MODELING PROCESS FOR TMDL DEVELOPMENT**

A key component in developing a TMDL is establishing the relationship between pollutant loadings (both point and nonpoint) and in-stream water quality conditions. Once this relationship is developed, management options for reducing pollutant loadings to streams can be assessed. In developing a TMDL, it is critical to understand the processes that affect the fate and transport of the pollutant(s) and that cause the impairment of the water body of concern. Pollutant transport to water bodies is evaluated using a variety of tools, including monitoring, geographic information systems (GIS), and computer simulation models. In the development of the sediment TMDLs for the Little Otter River and Buffalo Creek watersheds and the total phosphorus (TP) TMDL development for the Lower Little Otter River, the relationship between pollutant sources and pollutant loading to the stream was defined by land uses and areas assessed from the NASS 2009 cropland data layer, together with non-land based loads and simulated output from a computer watershed loading model. The modeling process, input data requirements, and TMDL load calculation procedures are discussed in this chapter.

### **6.1. Model Selection**

The model selected for development of the sediment TMDLs in the Little Otter River and Buffalo Creek watersheds and the TP TMDL in the Lower Little Otter Creek watershed was the Generalized Watershed Loading Functions (GWLF2010) model, originally developed by Haith et al. (1992), with modifications by Evans et al. (2001), Yagow et al. (2002), and Yagow and Hession (2007). The model was run in metric units and converted to English units for this report.

The loading functions upon which the GWLF model is based are compromises between the empiricism of export coefficients and the complexity of process-based simulation models. GWLF is a continuous simulation spatially-lumped parameter model that operates on a daily time step. The model estimates runoff, sediment, and dissolved and attached nitrogen and phosphorus loads delivered to streams from complex

watersheds with a combination of point and non-point sources of pollution. The model considers flow inputs from both surface runoff and groundwater. The hydrology in the model is simulated with a daily water balance procedure that considers different types of storages within the system. Runoff is generated based on the Soil Conservation Service's Curve Number method as presented in Technical Release 55 (SCS, 1986).

GWLF uses three input files for weather, transport, and nutrient data. The weather file contains daily temperature and precipitation for the period of simulation. The transport file contains input data primarily related to hydrology and sediment transport, while the nutrient file contains primarily nutrient values for the various land uses, point sources, and septic system types. The Penn State Visual Basic™ version of GWLF with modifications for use with ArcView was the starting point for additional modifications (Evans et al., 2001). The following modifications related to sediment were made to the Penn State version of the GWLF model, as incorporated in their ArcView interface for the model, AvGWLF v. 3.2:

- Urban sediment buildup was added as a variable input.
- Urban sediment washoff from impervious areas was added to total sediment load.
- Formulas for calculating monthly sediment yield by land use were corrected.
- Mean channel depth was added as a variable to the streambank erosion calculation.

The GWLF2006 version of GWLF (Yagow and Hession, 2007) was used in previous TMDL studies. The GWLF2006 version includes a correction to the flow accumulation calculation in the channel erosion routine that was implemented in December 2005 (VADEQ, 2005). This version also includes modifications from Schneiderman et al. (2002) to include an unsaturated zone leakage coefficient, to remove the annual boundary for transported sediment distribution, and to add in missing bounds for the calculation of erosivity using Richardson equations which were intended to have minimum and maximum bounds on daily calculations. These minimum and maximum bounds were not included in GWLF 2.0, and have been added to keep calculations within physically expected bounds. Delivered loads were also recoded as a function of transported, instead of detached, sediment. The current GWLF2010 version restored the original annual boundary for transported sediment distribution to correct a minor calculation error.

Erosion is generated using a modification of the Universal Soil Loss Equation. Sediment supply uses a delivery ratio together with the erosion estimates, and sediment transport takes into consideration the transport capacity of the runoff. Stream bank and channel erosion was calculated using an algorithm by Evans et al. (2003) as incorporated in the AVGWLF version (Evans et al., 2001) of the GWLF model and corrected for a flow accumulation coding error (VADEQ, 2005).

Nutrient loads are simulated as loading functions of either runoff or sediment loads and by point source, land use, groundwater, septic system, or stream channel erosion. Dissolved nutrients are simulated as loading functions of point sources, pervious land uses, groundwater, and septic systems, while particulate nutrients are simulated as loading functions of point sources, and of pervious and impervious land uses.

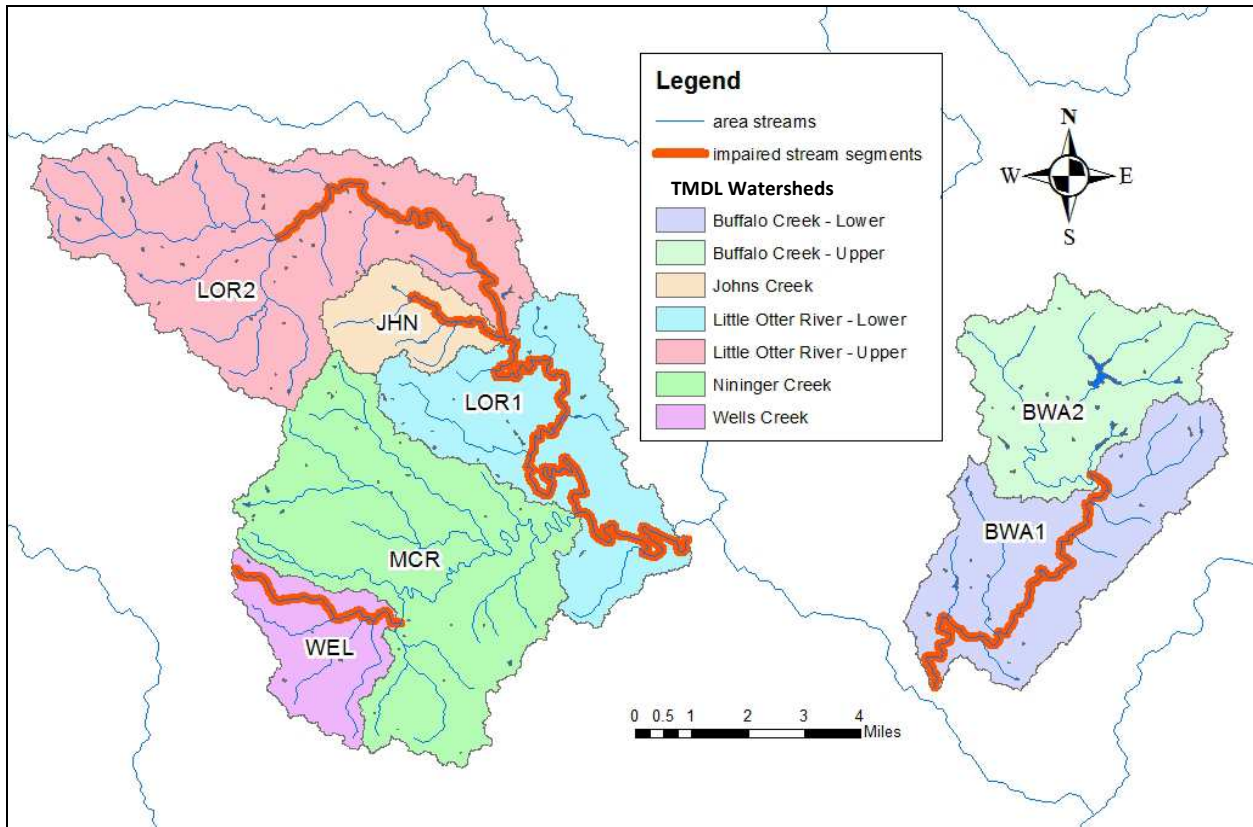

## **6.2. GWLF Model Development for Sediment**

Since simulated sediment loads were required from the comparison watersheds as well as from the TMDL watersheds in the Little Otter River and Buffalo Creek, model input data were created for each of the four comparison watersheds, for the four TMDL watersheds contributing to the impaired segments on the Little Otter River and its tributaries, and for the two TMDL watersheds contributing to the impaired segments on Buffalo Creek. Additionally, a portion of the Big Otter River watershed was used as a surrogate for calibrating hydrologic parameters. Model development for all watersheds was performed by assessing the sources of sediment in the watershed, evaluating the necessary parameters for modeling loads, calibrating to observed flow data, and finally applying the model and procedures for calculating loads.

Since some of the headwater watersheds are nested within downstream watersheds, the land segments were simulated uniquely, so that the land areas and associated loads do not overlap. For example, in the Buffalo Creek watershed, areas and associated loads from the Upper Buffalo Creek and Lower Buffalo Creek watersheds would need to be added together to sum for the entire watershed. Similarly in the Little Otter River watershed, the Upper Little Otter River, Johns Creek, and Wells Creek watersheds are all exclusive headwater segments, but the Lower Little Otter

River receives inputs from all three, so that areas and associated loads would need to be summed for all four watersheds to obtain totals for the Little Otter River.

The six impaired segments and the modeled TMDL watersheds are shown in **Error! Reference source not found..**

**Figure 6-1. TMDL Watersheds in Little Otter River and Buffalo Creek**

### **6.3. GWLF Model Development for Total Phosphorus**

The TP impairment on the Lower Little Otter River was determined to originate primarily from excess loads from the Bedford City WWTP. Since the discharge from the WWTP was at the confluence of the Upper Little Otter River and Johns Creek, and since a DEQ monitoring station (4ALOR014.33) sits a mere 100 yards downstream from the confluence, the TP TMDL for the Lower Little Otter River was developed for the watershed above station 4ALOR014.33 on the Lower Little Otter River. A diagram of the

various DEQ monitoring station location and that of the WWTP discharge point are shown in Figure 6-2.

**Figure 6-2. Locations of DEQ Monitoring Stations and the Bedford City WWTP**

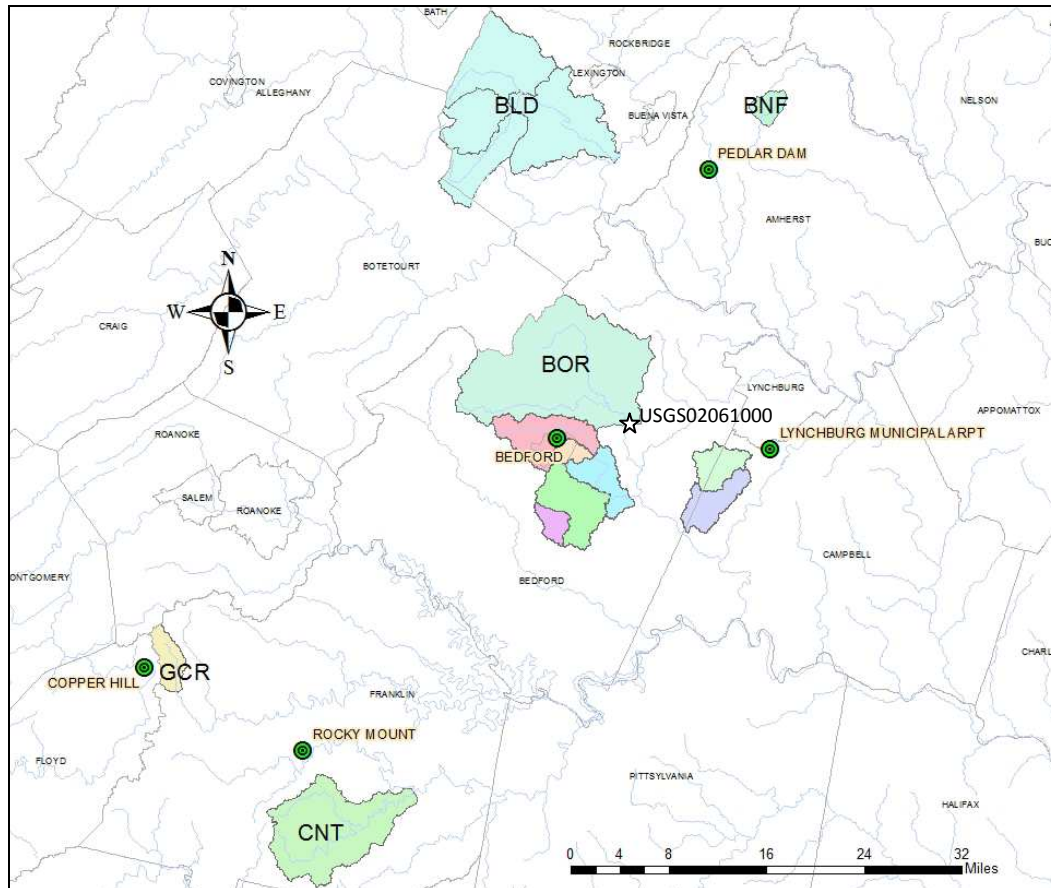

Model development for all watersheds was performed by assessing the sources of phosphorus in the watershed, evaluating the necessary parameters for modeling loads, applying the hydrologic calibration parameter adjustments, calibrating to average observed TP concentration data in each of the two upstream sub-watersheds above the WWTP, and finally applying the GWLF model and procedures for calculating loads. Since the area between the confluence of Johns Creek with the Upper Little Otter River and station 4ALOR014.33 was minimal (1 hectare) and primarily forested, the TP loads at station 4ALOR014.33 were represented as the sum of the loads from the Johns Creek (JHN) and Upper Little Otter River (LOR2) watersheds plus the load from the WWTP.

## **6.4. Input Data Requirements**

### **6.4.1. Climate Data**

The climate in Little Otter River and Buffalo Creek watersheds were characterized by meteorological observations from the National Weather Service Cooperative Station 440561 at Bedford, Virginia and Station 445120 at Lynchburg Regional Airport, respectively. For the comparison watersheds, the climate of the two James River watersheds - Buffalo Creek (BLD) and N.F. Buffalo River (BNF) used data from Station 446593 at Pedlar Dam, while Green Creek (GCR) used data from Station 441999 at Copper Hill and Big Chestnut Creek (CNT) used data from Station 447338 at Rocky Mount. The period of record used for TMDL modeling was a nineteen-year period from January 1992 through December 2010, with the preceding 9 months of data used to initialize storage parameters. The Big Otter River (BOR) watershed used for hydrologic calibration was simulated with the Bedford 440561 weather and compared with corresponding observed daily discharge from the USGS station 02061000 for the period January 2008 through December 2011. The locations of the various NCDC stations are shown in relationship to the Little Otter River, Buffalo Creek, the comparison watersheds, and the hydrologic calibration watershed in Figure 6-3.

**Figure 6-3. Location of Weather and Discharge Stations**

#### **6.4.2. Existing Land Use**

Modeled land uses for the Little Otter River, the Buffalo Creek, the hydrologic calibration, and the comparison watersheds were derived from the USDA National Agricultural Statistics Service digital cropland data layer for 2009, as discussed in Section 2.5. The NASS categories were consolidated into general land use categories of Row Crop, Hay, Pasture, Forest, and various “developed urban” categories, as shown in Table .

**Table 6-1. NASS Land Use Group Distributions**

		NASS Land Use Groups										
		Row Crop	Hay	Pasture	Forest	Barren	Urban open space	LDI	MDI	HDI	Water	Total
TMDL Watersheds		Area in acres										
Lower Buffalo Creek	BWA1	7.0	1,083.2	1,280.2	5,574.7	25.9	522.7	101.5	3.1	1.5	8.5	8,608.4
Upper Buffalo Creek	BWA2	55.8	1,176.0	844.2	2,416.9	103.5	1,424.6	877.2	179.8	33.3	88.3	7,199.6

LDI = low intensity developed; MDI = medium intensity developed; HDI = high intensity developed

The Row Crop category was subdivided into hi-till and low-till categories based on Conservation Tillage Information Center (CTIC) data as incorporated in the 2006 Virginia Statewide NPS Watershed Assessment (Yagow and Hession, 2007). The Hay and Pasture acreages were combined and reassigned based on percent distribution by VAHU6, also as used in the Yagow and Hession study (2007). From the Pasture category, the “riparian”, and “animal feeding operation” land uses were calculated as 0.0497 and 0.00582 times the total Pasture area, respectively, as estimated from proportions within the Chesapeake Bay Watershed Model (CBWM) land-river segment OR2\_7610\_7780. The remaining Pasture area was sub-divided into 10% “good”, 70% “fair”, and 20% “poor” pasture land uses, based on an assessment by local conservation personnel. A “harvested forest” land use was created as 1% of the Forest category, similar to procedures used in the CBWM (USEPA, 2010). The “barren” category was reassessed as 1.6% of all the developed land use categories for Buffalo Creek, as half that rate (0.8%) for Little Otter River sub-areas and as 0.4% for the less developed comparison and calibration watersheds, and subtracted from the “Urban Open Space” land use. Half of the “barren” areas were assumed to be subject to VSMP requirements, while the other half were assumed to be disturbed areas in parcels below the minimum size subject to VSMP permits. The “developed” categories were sub-divided into pervious and impervious portions, with “urban open space” assigned to the pervious

portion of the “low intensity developed” land use. Impervious percentages of 20%, 50%, and 80% were used, respectively, for the low intensity, medium intensity and high intensity developed areas. The simulated land uses and their derivations are summarized in Table , while detailed distributions are included in the appendix.

**Table 6-2. Modeled Land Use Categories**

<b>NASS Groups</b>	<b>NASS Land Uses</b>	<b>% Impervious</b>	<b>Modeled Land Use Categories</b>
Row Crop	Corn, sorghum, soybeans, winter wheat, etc.	0	Hi-till cropland
			Lo-till cropland
Hay	Alfalfa, other hays	0	Hay
Pasture	Pasture/grass, shrubland, grassland herbaceous	0	Good pasture
			Fair pasture
			Poor Pasture
			Riparian pasture
			Animal feeding operation
Forest	Deciduous forest, evergreen forest, mixed forest,	0	Forest
			Harvested forest
Barren	Barren	0	Barren
Open Space	Urban open space	0	Pervious LDI
LDI	Developed, low intensity	20	Impervious LDI
			Pervious LDI
MDI	Developed, medium intensity	50	Impervious MDI
			Pervious MDI
HDI	Developed, high intensity	80	Impervious HDI
			Pervious HDI

Each land use within a sub-watershed formed a hydrologic response unit (HRU). Model parameters were then calculated for each HRU using GIS analysis to reflect the variability in topographic and soil characteristics across the watershed. A description of model parameters follows in section 6.5.

## **6.5. Future Land Use**

A future land use scenario was created using the same land use categories as for the existing scenario. Future land use was assessed from a combination of the Bedford County Future Land Use spatial data layer associated with the Bedford County 2025 Comprehensive Plan, the City of Bedford 2012 Comprehensive Plan (no map), the Campbell County on-line GIS data layers for tax parcels and zoning, and the U.S.

Census Bureau data for the area in both 2000 and 2010. For those areas where spatial data were available, an assessment was made of current agricultural land (agland) and forest land zoned for development. Population change between 2000 and 2010 was then evaluated. Based on a combination of the 10-yr percent change in population, the potential for future agland reduction and forest land reduction, and a visual assessment of the availability of land already sub-divided into smaller parcels (Campbell County only), a percent reduction in agland and forest land was assigned to each sub-watershed, as shown in Table .

**Table 6-3. Future Land Use Change Assessment Summary**

Sub-watershed	Population			Total Area (acres)	Agland zoned for Development			Forest zoned for Development			Assigned Future Ag Reduction	Assigned Future Forest Reduction	Rationale
	2000	2010	10-yr percent change		Bedford County (acres)	Bedford City (acres)	Potential Future Ag Reduction	Bedford County (acres)	Bedford City (acres)	Potential Future Forest Reduction			
Buffalo Creek - Lower	2,435	2,741	12.60%	1,538.4	69.4	0.0	4.5%	147.7	0.0	9.6%	5.0%	20.0%	estimated as 2x the forest change% in Upper BWA + availability of small parcels*
Buffalo Creek - Upper	8,884	9,811	10.40%	2,941.0	0.0	0.0	0.0%	0.0	0.0	0.0%	0.0%	10.0%	used pop change% + availability of small parcels*
Johns Creek	2,456	2,414	-1.70%	2,680.6	125.9	174.7	11.2%	275.3	251.0	19.6%	11.0%	20.0%	estimated as % zoning change
Little Otter River - Lower	1,089	1,339	22.90%	8,906.8	92.4	9.9	1.1%	134.3	8.0	1.6%	1.0%	2.0%	estimated as % zoning change
Little Otter River - Upper	5,214	6,150	17.90%	14,696.4	1,790.3	565.3	16.0%	1,502.5	572.3	14.1%	16.0%	14.0%	estimated as % zoning change
Machine Creek	1,514	1,594	5.20%	14,166.3	420.0	12.9	3.1%	276.5	14.5	2.1%	3.0%	2.0%	estimated as % zoning change
Wells Creek	355	436	22.80%	3,560.7	0.0	0.0	0.0%	0.0	0.0	0.0%	0.0%	0.0%	all zoned agriculture - unlikely future change

Campbell County was assessed visually through their on-line GIS.

\* - Many parcels already sub-divided into small parcels in the Buffalo Creek watershed, suitable for development.

The future land use scenario was then constructed by reducing all agriculture and forestry land uses by their respective reduction percentages and redistributing the changed acreage on proportional basis to all developed land use categories. An additional change was added to account for a recent new development along Waterlick Road in the Upper Buffalo Creek watershed, with 4.96 acres of Urban Open Space changed to high intensity developed. Detailed tables of the land use distribution for the future land use scenario are included in the appendix.

## 6.6. GWLF Parameter Evaluation

All parameters were evaluated in a consistent manner for all watersheds in order to ensure their comparability. All GWLF parameter values were evaluated from a combination of GWLF user manual guidance (Haith et al., 1992), AVGWLF procedures

(Evans et al., 2001), procedures developed during the 2006 statewide NPS pollution assessment (Yagow and Hession, 2007), and best professional judgment.

Hydrologic and sediment parameters are all included in GWLF's transport input file, with the exception of urban sediment buildup rates, which are in the nutrient input file. Nutrient parameters are all included in GWLF's nutrient input file. Descriptions of each of the hydrologic, sediment, and nutrient parameters are listed below according to whether the parameters were related to the overall watershed, to the month of the year, or to individual land uses. The GWLF parameter values used for each of the Little Otter River, Buffalo Creek, comparison, and calibration watersheds are detailed in Appendix E.

### **6.6.1. Hydrology Parameters**

#### ***Watershed-Related Parameter Descriptions***

- Unsaturated Soil Moisture Capacity (SMC, cm): The amount of moisture in the root zone, evaluated as a function of the area-weighted soil type attribute - available water capacity.
- Recession coefficient (day<sup>-1</sup>): The recession coefficient is a measure of the rate at which streamflow recedes following the cessation of a storm, and is approximated by averaging the ratios of streamflow on any given day to that on the following day during a wide range of weather conditions, all during the recession limb of each storm's hydrograph. This parameter was evaluated using the following relationship from Lee et al. (2000):  $\text{RecCoeff} = 0.045 + 1.13/(0.306 + \text{Area in square kilometers})$
- Seepage coefficient: The seepage coefficient represents the fraction of flow lost as seepage to deep storage.
- Leakage coefficient: The leakage coefficient represents the fraction of infiltration that bypasses the unsaturated zone through macro-pore flow. An increase in this coefficient, initially set to zero, decreases ET losses and increases baseflow.

The following parameters were initialized by running the model for a 9-month period prior to the period used for load calculation:

- Initial unsaturated storage (cm): Initial depth of water stored in the unsaturated (surface) zone.
- Initial saturated storage (cm): Initial depth of water stored in the saturated zone.
- Initial snow (cm): Initial amount of snow on the ground at the beginning of the simulation.
- Antecedent Rainfall for each of 5 previous days (cm): The amount of rainfall on each of the five days preceeding the current day.

***Month-Related Parameter Descriptions***

- Month: Months were ordered, starting with April and ending with March - in keeping with the design of the GWLF model.
- ET CV: Composite evapotranspiration cover coefficient, calculated as an area-weighted average from land uses within each watershed.
- Hours per Day: Mean number of daylight hours.
- Erosion Coefficient: This is a regional coefficient used in Richardson's equation for calculating daily rainfall erosivity. Each region is assigned separate coefficients for the months October-March, and for April-September.

***Land Use-Related Parameter Descriptions***

- Curve Number: The SCS curve number (CN) is used in calculating runoff associated with a daily rainfall event, evaluated using SCS TR-55 guidance.

**6.6.2. Sediment Parameters**

***Watershed-Related Parameter Descriptions***

- Sediment delivery ratio: The fraction of erosion - detached sediment - that is transported or delivered to the edge of the stream, calculated as an inverse function of watershed size (Evans et al., 2001).

***Land Use-Related Parameter Descriptions***

- USLE K-factor: The soil erodibility factor was calculated as an area-weighted average of all component soil types.
- USLE LS-factor: This factor is calculated from slope and slope length measurements by land use. Slope is evaluated by GIS analysis, and slope length is calculated as an inverse function of slope.
- USLE C-factor: The vegetative cover factor for each land use was evaluated following GWLF manual guidance, Wischmeier and Smith (1978), and Hession et al. (1997); and then adjusted after consultation with local NRCS personnel.
- Daily sediment buildup rate on impervious surfaces: The daily amount of dry deposition deposited from the air on impervious surfaces on days without rainfall, assigned using GWLF manual guidance.

***Streambank Erosion Parameter Descriptions (Evans et al., 2003)***

- % Developed land: percentage of the watershed with urban-related land uses - defined as all land in MDR and HDR land uses, as well as the impervious portions of LDR.
- Animal density: calculated as the number of beef and dairy 1000-lb equivalent animal units (AU) divided by the watershed area in acres.
- Curve Number: area-weighted average value for the watershed.
- K Factor: area-weighted USLE soil erodibility factor for the watershed.
- Slope: mean percent slope for the watershed.
- Stream length: calculated as the total stream length of natural perennial stream channels, in meters.
- Mean channel depth (m): calculated from relationships developed either by the Chesapeake Bay Program or by USDA-NRCS by physiographic region, of the

general form:  $y = a * A^b$ , where  $y$  = mean channel depth in ft,  $A$  = drainage area in square miles, and “a” and “b” are regression coefficients (USDA-NRCS, 2005).

### **6.6.3. Nutrient Parameters**

#### ***Watershed-Related Parameter Descriptions***

- Sediment N and P (mg/kg): Soil-phase nutrients in sediment are estimated as sediment N and P. Sediment N and P are calculated for each nutrient as the soil N or P content multiplied by an N or P enrichment ratio.
- Groundwater N and P (mg/L): Mean concentrations of N and P in groundwater discharge.
- No. of Rural (Pervious) Land Uses Receiving Manure Applications: The number of agricultural land uses simulated as receiving applications of spread manure.
- Beg and End Months for Each of Two Manure Application Periods: A basic assumption in the model revision by Penn State is that there is a Spring period and a Fall period during which manure may be applied to the land. Each period is defined by a beginning and an ending month.

#### ***Landuse-Related Parameter Descriptions***

- Dissolved Nutrient Concentrations in Runoff (N, P) By Land Use (mg/L): These concentrations correspond to runoff from the respective land uses during periods without manure applications.
- Impervious Area Build-up Rates by Land Use: Sed (kg/ha-d), N and P (kg/kg Sed): These are the daily rates of pollutant build-up on the surface, on days without rainfall.
- Runoff N and P from Areas receiving Manure Applications (mg/L): These are landuse-specific concentrations of N and P that correspond to periods of manure application.

#### ***Month-Related Parameter Descriptions***

- Monthly Point Source Loads (N, P): Monthly loads of N and P from point sources may be entered with these parameters in units of kg/month. Point source loads for this assessment, however, were included in a post-processing step.
- Septic System Flag: This flag should be set to “1” if septic systems are to be simulated, and “0” if they are not. When set to “1”, the following three types of data are expected:
  - Septic System Monthly Population Distribution: This matrix of numbers represents the population distribution by month of persons in each of the four types of septic system categories - normal, ponded, short-circuited, and direct discharge systems as defined in the GWLF Manual (Haith et al., 1992).

- Normal system: a system whose construction, operation, and maintenance conform to recommended procedures and regulations.
- Ponded system: a system that exhibits hydraulic failure of the tank's absorption field resulting in the surfacing of the effluent.
- Short-circuited system: a system located so close (< 15m) to surface waters that negligible adsorption of phosphorus takes place. This category is not evaluated in this assessment.
- Direct-discharge system: a septic tank or straight pipe that transfers its effluent directly into surface waters.
- Septic System Effluent N and P (g/person-day): These values represent mean daily nutrient loads in the septic system effluent.
- Plant Nutrient Uptake N and P (g/day): The monthly rates of N and P uptake by plants are each specified by two values - one for months during the growing season, and one for months during the dormant season.

## **6.7. Supplemental Post-Model Processing**

After modeling was performed on individual and cumulative sub-watersheds, model output was post-processed in a Microsoft Excel™ spreadsheet to summarize the modeling results and to account for existing levels of BMPs already implemented within each watershed.

The extent and effect of existing agricultural BMPs in the TMDL watersheds were based on data extracted from Virginia DCR's online agricultural BMP database for each of the three sixth-order watersheds encompassing these watersheds, namely RU53 (Wells Creek and Machine Creek), RU54 (Upper and Lower Little Otter River and Johns Creek), and RU56 (Upper and Lower Buffalo Creek).

### ***Sediment***

The extent and effect of existing agricultural BMPs on the reference and calibration watersheds were based on the pass-through fractions of the sediment load from each land use in each HUP as developed by Virginia DCR previously for the Virginia 2006 Statewide NPS Pollution Assessment (Yagow and Hession, 2007).

Modeled sediment loads within each land use category were then multiplied by their respective pass-through fractions to simulate the reduced loads resulting from existing BMPs.

Since the dam on Timberlake was rebuilt recently (1995), it effectively serves as a sediment trap for upland areas in that watershed. The area draining into the lake was calculated as 1,221.26 ha of the total area of 2,939.55 ha in the Upper Buffalo Creek watershed. A sediment trapping efficiency of 50% was then additionally applied to this fraction of the watershed and associated sediment loads.

Sediment BMPs are required on harvested forest lands and on disturbed lands subject to Erosion and Sediment (E&S) regulations. A sediment efficiency of 25.5% was used for BMPs on harvested forest land (USEPA, 2010), while sediment reductions on half of the existing disturbed land was assumed to be subject to E&S permits at a sediment efficiency of 40%.

### ***Total Phosphorus***

The extent and effect of existing agricultural BMPs, TP-related BMPs called for in the Big Otter River IP, and TP-related sediment reductions on the Lower Little Otter River sub-watersheds were based on land use changes and calculated pass-through fractions of the TP load from each land use. BMP Scenario 1 includes existing BMPs plus those TP-related BMPs called for in the Big Otter River Implementation Plan; BMP Scenario 2 includes BMP Scenario 1 BMPs plus TP reductions associated with sediment reductions called for in the Little Otter River sediment TMDLs (this document). A summary of BMPs considered under each reduction scenario are shown in Table 6-4 and the aggregate pass-through efficiencies in Table 6-5.

**Table 6-4. Summary of BMPs and Area Treated under Three TP Reduction Scenarios**

BMP Description	BMP Mechanism	Existing BMPs 9/4/12		BMP Scenario 1		BMP Scenario 2	
		Upper Little Otter River	Johns Creek	Upper Little Otter River	Johns Creek	Upper Little Otter River	Johns Creek
		Area in acres					
Forest Buffer	Land Use Change	7.4	3.4	7.4	3.4	7.4	3.4
Upland Cropland Buffered by Forest Buffers (TP)	Efficiency	14.9	6.8	14.9	6.8	14.9	6.8
Reforested cropland	Land Use Change	0.8	0.4	0.8	0.4	0.8	0.4
Grazing Land Protected	Efficiency	742.0		1,662.9	117.7	2,644.1	119.5
Livestock Exclusion Buffers	Land Use Change	81.6		218.8	15.5	218.8	15.5
Upland Pasture Buffered by Livestock Exclusion (TP)	Efficiency	163.1		437.5	31.0	437.5	31.0
Various nutrient load reduction practices	Efficiency					2,011.8	502.3

**Table 6-5. Summary of TP Pass-Through Factors by Reduction Scenario and Land Use**

Applicable Land Use	Existing BMPs 9/4/12		BMP Scenario 1		BMP Scenario 2	
	Upper Little Otter River	Johns Creek	Upper Little Otter River	Johns Creek	Upper Little Otter River	Johns Creek
cropland	0.9320	0.8871	0.9320	0.8871	0.9320	0.8871
pasture	0.9317	1.0000	0.8376	0.8358	0.7668	0.8340
developed					0.3640	0.5910
livestock-direct deposit	0.6272	1.0000	0.0000	0.0000	0.0000	0.0000

## 6.8. Representation of Sediment Sources

Sediment is generated in the Little Otter River and Buffalo Creek watersheds through the processes of surface runoff, in-channel disturbances, and streambank and channel erosion, as well as from natural background contributions and permitted sources. Sediment generation is accelerated through human-induced land-disturbing activities related to a variety of agricultural, forestry, mining, transportation, and residential land uses.

Permitted sediment dischargers in Buffalo Creek and Little Otter River include both stormwater and point source facilities. Stormwater discharges include construction permits regulated through Virginia's Erosion and Sediment Control Program and urban stormwater runoff from MS4, municipal, industrial and general permits. Point source

dischargers include individual VPDES facilities, as well as those that fall under the broader aggregate General Permits.

#### **6.8.1. Surface Runoff**

During runoff events, sediment loading occurs from both pervious and impervious surfaces around the watershed. For pervious areas, soil is detached by rainfall impact or shear stresses created by overland flow and transported by overland flow to nearby streams. This process is influenced by vegetative cover, soil erodibility, slope, slope length, rainfall intensity and duration, and land management practices. During periods without rainfall, dirt, dust and fine sediment build up on impervious areas through dry deposition, which is then subject to washoff during rainfall events. Pervious area sediment loads were modeled using a modified USLE erosion detachment algorithm, monthly transport capacity calculations, and a sediment delivery ratio in the GWLF model to calculate loads at the watershed outlet. Impervious area sediment loads were modeled in the GWLF model using an exponential buildup-washoff algorithm.

#### **6.8.2. Channel and Streambank Erosion**

Streambank erosion was modeled within the GWLF model using a modification of the routine included in the AVGWLF version of the GWLF model (Evans et al., 2001). This routine calculates average annual streambank erosion as a function of percent developed land, average area-weighted curve number (CN) and K-factors, watershed animal density, average slope, streamflow volume, mean channel depth, and total stream length in the watershed. Livestock population, which figures into animal density, was estimated based on a stocking density of 0.167 animal units per acre of available pasture (AU/acre).

#### **6.8.3. Industrial Stormwater**

Currently, there are six (6) active Industrial Storm Water General Permits (ISWGP) in the Little Otter River watersheds, and one (1) in the Buffalo Creek watersheds. Current loads for each facility were simulated as part of the urban pervious and impervious land use categories. Permitted WLA loads for each facility were calculated as the permitted area of the facility times the permitted average TSS

concentration of 100 mg/L times the average annual runoff (simulated for low intensity developed areas), as shown in Table .

**Table 6-6. Industrial Stormwater General Permit (ISWGP) WLA Loads**

Facility Name	VPDES Permit Number	Source Type	Receiving Stream	Area (acres)	Permitted Average TSS Concentration (mg/L)	Average Annual Runoff (in/yr)	TSS WLA (tons/yr)
Sam Moore Furniture LLC	VAR050528	ISWGP	Johns Creek	20	100	19.05	4.32
Hilltop Lumber Co Inc	VAR050544	ISWGP	Upper Little Otter River	11.87	100	19.05	2.56
Rubatex International LLC	VAR050733	ISWGP	Johns Creek	7.27	100	19.05	1.57
Bedford County - Sanitary Landfill	VAR051233	ISWGP	Machine Creek UT	52	100	19.05	11.22
Bedford City - Hylton Site	VAR051369	ISWGP	Johns Creek	20	100	19.05	4.32
Central VA Pallet and Stake Co	VAR052107	ISWGP	Upper Little Otter River	11.73	100	19.05	2.53
New London Auto Parts Inc	VAR051801	ISWGP	Lower Buffalo Creek	19.05	100	16.86	3.64

Load = X acres \* Y mg/L \* Z in/yr \* 102,801.6 L/acre-inch \* 1 lb/453,600 mg \* 1 ton/2000 lbs = X \* Y \* Z \* 0.000113317 tons/yr

#### **6.8.4. Construction Stormwater**

Between January 2008 and June 2012, there have been 10 land disturbing (construction stormwater) permits issued in the Bedford County portion of the Buffalo Creek watersheds representing a total disturbed acreage of 17.04 acres. Of those permits, 4 are current, comprising a total of 8.34 acres. In the Campbell County portion of the Buffalo Creek watersheds, local construction permits were reported since 2010, totaling 35.13 acres of disturbed land, of which 23.3 acres were for single family construction and the rest for commercial construction.

In the Little Otter River watersheds, there have been 29 land disturbing (construction stormwater) permits issued between January 2008 and June 2012, representing a total disturbed acreage of 35.60 acres. Of those permits, 6 are current, comprising a total of 3.25 acres. Additional local construction permits for areas < 5 acres in size may also exist for single family construction and other small-scale construction.

Based on the more complete reported data in the Buffalo Creek watershed, barren land was calculated as a percentage of developed land in that watershed (0.79%), rounded to 0.80%, and applied to both the Upper and Lower Buffalo Creek watersheds. Since development rates were lower in the Little Otter River, with current reported rates suspected to be low, they were estimated as half of the rate (0.40% of developed land) in the Buffalo Creek watersheds and applied to the developed land in

each Little Otter River sub-area. Aggregated construction WLA loads for each sub-watershed were calculated as the permitted area times the permitted average TSS concentration of 60 mg/L times the simulated average annual runoff for the “barren” land use, as shown in Table .

**Table 6-7. Aggregated Construction WLA Loads**

Receiving Stream	Area (acres)	Permitted Average TSS Concentration (mg/L)	Average Annual Runoff (in/yr)	Aggregated TSS Load (tons/yr)
Lower Buffalo Creek	5.24	60	14.94	0.53
Upper Buffalo Creek	20.95	60	14.94	2.13
Lower Little Otter River	3.65	60	15.76	0.39
Machine Creek	4.18	60	15.76	0.45
Wells Creek	0.83	60	15.76	0.09
Johns Creek	4.91	60	15.76	0.53
Upper Little Otter River	12.65	60	15.76	1.36

#### **6.8.5. Municipal Stormwater**

There is one MS4 permit in the Upper Buffalo Creek watershed assigned to the Virginia Department of Transportation which includes its right-of-way (and properties) in the census-defined urbanized areas. The MS4 area, for the purposes of this report, was defined as the length of major roads within the 2010 census urbanized area in the watershed times a 20-meter (66-foot) buffer to include right-of-way. For Existing conditions, the associated sediment load is simulated as part of the medium intensity developed land use. For future conditions, the MS4 WLA was calculated as the estimated area times a benchmark TSS concentration times the simulated average annual runoff for the medium intensity developed land use, as shown in Table .

**Table 6-8. MS4 WLA Load**

VPDES Permit Number	Receiving Stream	Area (acres)	Benchmark TSS Concentration (mg/L)	Average Annual Runoff (in/yr)	TSS WLA (tons/yr)
Virginia DOT VA040115	Upper Buffalo Creek	40.19	60	25.45	6.95

### 6.8.6. Other Permitted Sources (VPDES and General Permits)

There are no general discharge permits for single-family homes in any of these watersheds, and no VPDES permits in the Buffalo Creek watersheds.

In the Little Otter River watersheds, there are two VPDES permits, one general permit, and one integrated discharge permit for a concrete facility. The Existing sediment loads from these sources was calculated as the average daily flow and average daily total suspended solids (TSS) concentration, as reported by the permit holders to DEQ in monthly discharge reports, as shown in Table . No discharge was reported for the concrete facility.

**Table 6-9. Existing Sediment Load from Other Permitted Sources**

Facility Name	Permit Number	Permit Type	Receiving Stream	Existing Conditions		
				Average Flow (MGD)	Average [TSS] (mg/L)	TSS Load (tons/yr)
Body Camp Elementary School	VA0020818	VPDES	Wells Creek	0.002	5.0	0.02
Bedford City - WWTP	VA0022390	VPDES	Upper Little Otter River	1.0	7.6	11.57
Bedford City - WTP	VAG640066	General	Upper Little Otter River UT	0.033	0.0	0.00
Bedford Ready Mix Concrete	VAG110014	Concrete	Johns Creek	0.0072	--	--

$$\text{Load} = X \text{ mgd} * Y \text{ mg/L} * 10^6 \text{ gal/MG} * 3.785411 \text{ L/gal} * 1.1022927 \text{ e}^{-9} \text{ lbs/mg} * 365 \text{ days/yr} = X * Y * 1.523 = Z \text{ tons/yr}$$

For the TMDL calculations, the waste load allocation (WLA) was calculated from the permitted average TSS concentration and the design flow for each facility. Where the design flow was not specified, the average daily flow was used for the load calculation. The WLA loads for each facility are shown in Table .

**Table 6-10. WLA Sediment Loads from Other Permitted Sources**

Facility Name	Permit Number	Permit Type	Receiving Stream	Permitted Conditions		
				Design Flow (MGD)	Permitted Average [TSS] (mg/L)	TSS WLA* (tons/yr)
Body Camp Elementary School	VA0020818	VPDES	Wells Creek	--	30	0.10
Bedford City - WWTP	VA0022390	VPDES	Upper Little Otter River	2.0	30	91.38
Bedford City - WTP	VAG640066	General	Upper Little Otter River UT	--	30	1.51
Bedford Ready Mix Concrete	VAG110014	Concrete	Johns Creek	0.0072	30	0.33

\* Where permitted flow limits are not specified, average daily flow is used for load calculation.

$$\text{Load} = X \text{ mgd} * Y \text{ mg/L} * 10^6 \text{ gal/MG} * 3.785411 \text{ L/gal} * 1.1022927 \text{ e}^{-9} \text{ lbs/mg} * 365 \text{ days/yr} = X * Y * 1.523 = Z \text{ tons/yr}$$

## 6.9. Representation of Total Phosphorus Sources

While TP is generated in the Lower Little Otter River watershed from natural background sources, TP loads are accelerated through human-induced land-disturbing

activities related to a variety of agricultural, forestry, mining, transportation, and residential land uses, including direct deposition of manure in-stream, buildup in soils from fertilization and subsequent transport through surface runoff, in-channel disturbances, streambank and channel erosion, permitted source discharges, and septic systems.

Although there are no current permitted sources of TP above station 4ALOR014.33, the Bedford City WWTP has documented elevated TP concentrations in its effluent in both its 2007 and 2013 permit applications to DEQ, which show it to be a major contributor of total phosphorus loads to the impaired segment (Table 3-29).

### **6.9.1. Direct Deposition from Livestock**

Phosphorus in direct deposits was simulated in a post-processing step based on the distribution of beef and dairy animal units (AU) with stream access, back-calculated from monthly sub-watershed fecal coliform loads presented in the Big Otter River Bacteria TMDL (Mostaghimi et al., 2000) and applying standard daily manure TP production rates of 0.094 and 0.092 lbs P/AU-day for dairy and beef, respectively (ASAE, 2003), as shown in Table 6-11. Monthly TP loads from this source (lbs P/month) were calculated by multiplying the number of livestock with stream access (AU) times the daily manure TP production rate (lbs P/AU-day) times the number of days per month,

**Table 6-11. Livestock Direct Deposition of Total Phosphorus In-stream**

Month	Livestock Direct Deposit In-stream			
	JHN	LOR2	JHN	LOR2
	(AU/month)		(lbs P/month)	
January	0.20	1.06	0.57	3.03
February	0.20	1.06	0.52	2.74
March	0.20	1.08	0.58	3.10
April	0.30	1.61	0.83	4.45
May	0.40	2.15	1.15	6.15
June	0.80	4.28	2.21	11.86
July	0.80	4.28	2.29	12.25
August	0.80	4.28	2.29	12.25
September	0.40	2.15	1.11	5.96
October	0.30	1.61	0.86	4.60
November	0.20	1.08	0.56	3.00
December	0.20	1.06	0.57	3.03

### **6.9.2. Surface Runoff**

During runoff events, phosphorus loading occurs from both pervious and impervious surfaces. For pervious areas, phosphorus is transported attached to soil particles detached by rainfall impact or shear stresses created by overland flow and transported by overland flow to nearby streams. This process is influenced by vegetative cover, soil erodibility, slope, slope length, rainfall intensity and duration, fertilization levels, and land management practices. During periods without rainfall, dirt, dust and fine sediment and attached phosphorus build up on impervious areas through dry deposition, which is then subject to washoff during rainfall events. Phosphorus attached to sediment from surface runoff is represented in the GWLF model as loading functions by landuse or source. Phosphorus also is transported in the dissolved phase and is represented in the model as loading functions for the various land uses, groundwater flow, and septic systems. The various P loading parameters are detailed in Appendix E.

### **6.9.3. Channel and Streambank Erosion**

Streambank erosion was modeled within the GWLF model using a modification of the routine included in the AVGWLF version of the GWLF model (Evans et al., 2001). This routine calculates average annual streambank erosion as a function of percent developed land, average area-weighted curve number (CN) and K-factors, watershed animal density, average slope, streamflow volume, mean channel depth, and total stream length in the watershed. Streambank phosphorus was simulated as a loading function of streambank erosion.

### **6.9.4. Permitted Sources**

In the TP TMDL watersheds, there are five Industrial Storm Water General Permits (ISWGP), two VPDES permits, one general permit, and one integrated discharge permit for a concrete facility, as shown previously in Table 2-27. None of these facilities have either monitoring requirements or specified phosphorus limits at the present time. Phosphorus loads from the Bedford City WWTP were represented as monthly flows reported in monthly Discharge Monitoring Reports (DMR) submitted to DEQ multiplied by monthly TP concentrations, derived from a monthly interpolation

between average daily TP concentrations recorded on their permit renewal applications in 2007 and 2013.

#### **6.9.5. Septic System Sources**

Septic system contributions to TP loads were quantified in GWLF based on the total non-sewered households and those households with failing septic systems as reported by sub-watershed for the Little Otter River watershed in the Big Otter Bacteria TMDL report (Mostaghimi et al., 2000). Total estimated non-sewered households were 114 and 417 in Johns Creek and Upper Little Otter River, respectively; while the estimated households with failing septic systems were 24 and 93, respectively. An average household size of 2.5 persons per house was used to estimate population.

### **6.10. Hydrologic Calibration**

Model calibration is the process of adjusting model parameter values so that simulated loads from a watershed are more comparable to loads calculated from corresponding monitored (“observed”) flow and concentration data at a given point in a stream. Although GWLF was originally developed for use in non-gaged watersheds and, therefore, does not require calibration, hydrologic calibration has been recommended where observed flow data is available (Dai et al., 2000). In-stream observed discharge data were not available in any of the Little Otter River or Buffalo Creek sub-watersheds, but were available in a similar-sized neighboring watershed, the Big Otter River. Hydrologic calibration was performed using this surrogate watershed, and the calibration adjustments applied to all of the Little Otter River, Buffalo Creek and comparison watersheds for the TMDL modeling. Details of the hydrologic calibration are provided in Appendix D.

### **6.11. Total Phosphorus Calibration**

To calibration was performed separately on Johns Creek and on Upper Little Otter Creek. Observed in-stream TP concentration data were available at DEQ ambient monitoring stations 4AJHN000.01 on Johns Creek from May 2009 through November 2011 and at 4ALOR014.75 on the Upper Little Otter River from February 2007 through

April 2012. TP calibration was performed by adjusting various dissolved and particulate loading functions until the average simulated concentration (calculated as total TP load divided by total flow) for an 8-year period, 2004 through 2011, approximately matched with the average observed concentration at each station. More details on the TP calibration are provided in Appendix D.

## **6.12. Accounting for Critical Conditions and Seasonal Variations**

### **6.12.1. Selection of Representative Modeling Period**

Sediment: Selection of the modeling period was based on the availability of daily weather data and the need to represent variability in weather patterns over time in the watershed. A long period of weather inputs was selected to represent long-term variability in the watershed. The model was run using a weather time series from April 1991 through December 2010, with the first 9 months used as an initialization period for internal storages within the model. The remaining 19-year period was used to calculate average annual sediment loads in all watersheds.

Phosphorus: The modeling period was selected to correspond with the period of complete year DMR records for the WWTP and also to be representative of expected variability in weather patterns. The model was run using a weather time series from April 2003 through December 2011, with the first 9 months used as an initialization period for internal storages within the model. The remaining 8-year period was used to calculate average total phosphorus concentrations at the station 4ALOR014.33.

### **6.12.2. Critical Conditions**

The GWLF model is a continuous simulation model that uses daily time steps for weather data and water balance calculations. The period of rainfall selected for modeling was chosen as a multi-year period that was representative of typical weather conditions for the area, and included “dry”, “normal” and “wet” years. The model, therefore, incorporated the variable inputs needed to represent critical conditions during low flow - generally associated with point source loads - and critical conditions during high flow - generally associated with nonpoint source loads.

### 6.12.3. Seasonal Variability

The GWLF model used for this analysis considered seasonal variation through a number of mechanisms. Daily time steps were used for weather data and water balance calculations. The model also used monthly-variable parameter inputs for evapo-transpiration cover coefficients, daylight hours/day, and rainfall erosivity coefficients for user-specified growing season months.

### 6.13. Existing Sediment Loads

Existing sediment loads were simulated for all individual land uses with the calibrated GWLF model and calculated for point sources, as discussed previously. The resulting loads in all TMDL and comparison watersheds are given in Table .

**Table 6-12. Existing Sediment Loads in TMDL and Comparison Watersheds**

### 6.14. Future Sediment Loads

Future sediment loads were simulated for all land use categories with the calibrated GWLF model with permitted sources calculated at their WLA permit limits, as

discussed previously. Since future sediment loads are considered to be the starting loads from which reductions will be required to meet the TMDLs, modeling of the future land uses was only performed on the TMDL watersheds. The resulting future sediment loads, shown in Table , are simulated from assessed future land use changes from agriculture and forestry to developed land uses.

**Table 6-13. Future Sediment Loads in TMDL Watersheds**

## 6.15. Existing Total Phosphorus Loads

Existing TP loads were simulated for all individual land uses with the calibrated GWLF model including existing BMPs and added to those calculated for direct deposition and point sources, as discussed previously. The resulting loads from the two component watersheds, including the WWTP, are given in Table 6-14.

**Table 6-14. Existing Total Phosphorus Loads above 4ALOR014.33**

Land Use/ Source Categories	Johns Creek	Upper Little Otter River	WWTP	Total

## Chapter 7: TMDLS AND ALLOCATIONS

The objective of a TMDL is to allocate allowable loads among different pollutant sources so that appropriate actions can be taken to achieve water quality standards (USEPA, 1991). The stressor analysis in each of the Buffalo Creek and Little Otter River watersheds indicated that sediment was the “most probable stressor”, and therefore, sediment will serve as the basis for development of these TMDLs. The AllForX approach was used to set appropriate sediment TMDL endpoints and to quantify the MOS for each TMDL watershed (see Appendix F for more details).

In addition to the sediment stressor, total phosphorus was also identified as an additional stressor in the Lower Little Otter River. The 90th percentile in-stream TP concentration (0.070 mg/L) from a nearby non-impaired watershed was used as the TP endpoint.

### 7.1. Buffalo Creek and Little Otter River Sediment TMDLs

#### 7.1.1. TMDL Components

The sediment TMDL for each of the Buffalo Creek and Little Otter River watersheds was calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

where  $\sum \text{WLA}$  = sum of the wasteload (permitted) allocations;

$\sum \text{LA}$  = sum of load (nonpoint source) allocations; and

MOS = margin of safety.

The sediment TMDL load for each TMDL watershed was calculated as the value of AllForX (13.64), the point where the regression line between AllForX and the VSCI intersected the VSCI impairment threshold (VSCI = 60), times the all-forest sediment load of each TMDL watershed. Details of the derivation of AllForX for the TMDL and comparison watersheds are provided in Appendix F.

The WLA in each watershed is comprised of sediment loads from a number of individual industrial stormwater, municipal, and commercial permitted sources, as well

as aggregated loads from construction runoff in each watershed. In addition, a Future Growth WLA was calculated as a portion of existing WLAs in each watershed, excluding construction, plus a portion of existing WWTP WLAs, with a minimum allowance of 0.1% of the TMDL.

An explicit MOS for each TMDL watershed was also calculated using the AllForX method. The 80% confidence interval was developed around the chosen value of AllForX, based on the number of watersheds included in the regression and the standard deviation of their AllForX values. The MOS was set equal to the difference between the value of AllForX at VSCI = 60 and the value of AllForX at the lower confidence interval limit, multiplied times the all-forest sediment load for each watershed.

The LA was calculated as the TMDL minus the sum of WLA and MOS. The TMDL load and its components for each TMDL watershed are shown in Table .

**Table 7-1. Buffalo Creek and Little Otter River Sediment TMDLs**

### 7.1.2. Maximum Daily Loads

The USEPA (2006a) has mandated that TMDL studies submitted since 2007 include a maximum “daily” load (MDL), in addition to the average annual loads shown in Section 7.1.1. The approach used to develop these MDLs was provided in Appendix B of a related USEPA guidance document (USEPA, 2006b). This appendix entitled “Approaches for developing a Daily Load Expression for TMDLs computed for Longer Term Averages” is dated December 15, 2006. This guidance provides a procedure for calculating an MDL (tons/day) for each watershed and pollutant from the long-term

average (LTA) annual TMDL load (tons/yr) and a coefficient of variation (CV) based on annual loads over a period of time. The “LTA to MDL multipliers” for Buffalo Creek and Little Otter River were calculated from the 1992-2010 simulated output of annual sediment loads using the calibrated GWLF model.

Annual simulated sediment loads for Buffalo Creek ranged from 1,549 to 15,911 tons/yr, producing a coefficient of variation (CV) = 0.61. The “LTA to MDL” multiplier was then interpolated from the USEPA guidance and calculated as 5.609 for both of the TMDL sub-watersheds contributing to Buffalo Creek. The MDL was calculated as the TMDL divided by 365 days/yr and multiplied by 5.609.

Annual simulated sediment loads for Little Otter River ranged from 5,840 to 49,009 tons/yr, producing a coefficient of variation (CV) = 0.47. The “LTA to MDL” multiplier was then interpolated from the USEPA guidance and calculated as 4.453 for all four TMDL sub-watersheds contributing to Little Otter River. The MDL was calculated as the TMDL divided by 365 days/yr and multiplied by 4.453.

Since the WLA represents permitted loads, no multiplier was applied to these loads. Therefore the daily WLA and components were converted to daily loads by dividing by 365 days/yr. The daily LA was calculated as the MDL minus the daily WLA minus the daily MOS. The resulting sediment MDL and associated components for the two Buffalo Creek segments and the six Little Otter River segments are shown in Table in units of tons/day.

Expressing the TMDL as a daily load does not interfere with a permit writer’s authority under the regulations to translate that daily load into the appropriate permit limitation, which in turn could be expressed as an hourly, weekly, monthly or other measure (USEPA, 2006a).

## 7.2. Sediment Allocation Scenarios

The target allocation sediment load for each watershed allocation scenario is the TMDL minus the MOS. Allocation scenarios were created by applying percent reductions to the various land use/source categories until the target allocation load was achieved for each of the Buffalo Creek and Little Otter River watersheds.

Two allocation scenarios were created for each of the watersheds. Scenario 1 applies equal percent reductions from all land uses and sources, except forest and point sources. Scenario 2 applies equal percent reductions from only the two largest sources

in each watershed. The preferred scenario for each watershed will be determined by the local Technical Advisory Committee. Future sediment loads along with two allocation scenarios are presented by grouped land uses and sources for the Lower Buffalo Creek in Table ; Upper Buffalo Creek in Table ; for the Lower Little Otter River in Table ; for Johns Creek in Table ; for Wells Creek in Table ; and for the Upper Little Otter River in Table .

### **7.3. Lower Little Otter River Total Phosphorus TMDL**

TP has been diagnosed as the most probable stressors in the Lower Little Otter River. Specifically, between DEQ monitoring stations 4ALOR014.75 and 4ALOR014.33, average TP increased from 0.072 to 0.440 mg/L from station 4ALOR014.75 to 4ALOR014.33, respectively. The source of this increase is most likely the Bedford City WWTP (VPDES #VA0022390). Prior to 2012, frequent exceedences of the in-stream TP threshold of 0.2 mg/L have been noted at DEQ station 4ALOR014.33, downstream from

the Bedford City WWTP. It should be noted that the Bedford City WWTP was not required to monitor TP at their effluent outfall. However, in 2012, as part of the permit renewal application, monitoring was required for several water quality parameters, including TP. The average TP concentration recorded by the WWTP on its permit applications was 3.0 mg/L from 3 samples in 2007 and 2.2 mg/L from 3 samples in 2013. Since the dominant source of TP is a point source, the Bedford City WWTP, and since monitoring is available on both Johns Creek and the Upper Little Otter River above the WWTP and on the Lower Little Otter River below the WWTP, this TMDL is being developed at the monitoring point on the Lower Little Otter River, station 4ALOR014.33. This station, which is near the upstream limit of the Lower Little Otter River impaired segment, therefore, does not include surface loading from the Lower Little Otter River watershed.

### **7.3.1. TMDL Components**

The total phosphorus TMDL for the Lower Little Otter River watershed was calculated using the following equation:

$$\text{TMDL} = \sum \text{WLA} + \sum \text{LA} + \text{MOS}$$

where  $\sum \text{WLA}$  = sum of the wasteload (permitted) allocations;

$\sum \text{LA}$  = sum of load (nonpoint source) allocations; and

MOS = margin of safety.

The TP TMDL load was calculated as the average annual load corresponding to an average annual in-stream concentration of 0.07 mg/L. This endpoint was based on the 90<sup>th</sup> percentile concentration of data collected at 4ABOR033.22, a neighboring non-impaired watershed on the Big Otter River.

Although there are currently no permitted sources of TP in the watershed, the recommendation is to add TP permit limits to the Bedford City WWTP that specify an average annual effluent TP concentration of 0.5 mg/L. This effluent concentration is consistent with effluent limits applied to significant municipal WWTP dischargers in the James River.

The MOS was considered to be implicit based on simulated loads calibrated to available in-stream monitoring data on both Johns Creek and the Upper Little Otter River above their confluence and the low coefficient of variation in annual loads.

The LA was calculated as the TMDL minus the sum of WLA and MOS. The TMDL load and its components for the Lower Little Otter River watershed are shown in Table .

**Table 7-9. Lower Little Otter River Total Phosphorus TMDL**

<b>TMDL</b>	<b>WLA</b>	<b>LA</b>	<b>MOS</b>
<b>(lbs/yr)</b>			
3,655.6	1,523.0	2,132.6	0.0
	VA0022390 Bedford City - WWTP 1,523.0		

### **7.3.2. Maximum Daily Loads**

The USEPA (2006a) has mandated that TMDL studies submitted since 2007 include a maximum “daily” load (MDL), in addition to the average annual loads shown in Section 7.3.1. The approach used to develop these MDLs was provided in Appendix B of a related USEPA guidance document (USEPA, 2006b). This appendix entitled “Approaches for developing a Daily Load Expression for TMDLs computed for Longer Term Averages” is dated December 15, 2006. This guidance provides a procedure for calculating an MDL (tons/day) for each watershed and pollutant from the long-term average (LTA) annual TMDL load (tons/yr) and a coefficient of variation (CV) based on annual loads over a period of time. The “LTA to MDL multipliers” for the Lower Little Otter River were calculated from the 2004-2011 simulated output of annual total phosphorus loads using the calibrated GWLF model.

Annual simulated total phosphorus loads at station 4ALOR014.33 on the Lower Little Otter River ranged from 3,383 to 5,012 lbs/yr, producing a coefficient of variation (CV) = 0.142. The “LTA to MDL” multiplier was then interpolated from the USEPA guidance and calculated as 1.204 for the Lower Little Otter River. The MDL was calculated as the TMDL divided by 365 days/yr and multiplied by 1.204.

Since the WLA represents proposed permitted loads, no multiplier was applied to these loads. Therefore the daily WLA and components were converted to daily loads by dividing by 365 days/yr. The daily LA was calculated as the MDL minus the daily WLA

minus the daily MOS. The resulting total phosphorus MDL and associated components for the Lower Little Otter River watershed is shown in Table in units of lbs/day.

Expressing the TMDL as a daily load does not interfere with a permit writer's authority under the regulations to translate that daily load into the appropriate permit limitation, which in turn could be expressed as an hourly, weekly, monthly or other measure (USEPA, 2006a).

**Table 7-10. The Lower Little Otter River Maximum "Daily" Total Phosphorus Load**

<b>MDL</b>	<b>WLA</b>	<b>LA</b>	<b>MOS</b>

12.06	4.17	7.89	0.00
	VA0022390 Bedford City - WWTP 4.17		

#### **7.4. Phosphorus Allocation Scenario**

The target allocation TP load for the Lower Little Otter River at station 4ALOR014.33 in the allocation scenarios is the TMDL minus the MOS. Progressive scenarios were developed to show the impact of planned BMPs on TP loads from the Big Otter bacteria Implementation Plan (VT-BSE, 2006), from reductions called for in the Little Otter River sediment TMDLs (this document), and from two alternate proposed effluent limits for the Bedford City WWTP, which would lead to sufficient reductions to meet the in-stream concentration endpoint under current flow rates from the WWTP. Future total phosphorus loads along with progressive reduction scenarios are presented in Table 7-11, along with two alternate Allocation Scenarios that satisfy the TMDL. Allocation Scenario 1 would satisfy the TMDL based on current average daily flow from the WWTP and a 0.5 mg/L TP effluent limit. Allocation Scenario 2 meets the TMDL by allowing for expansion to the full design flow at the WWTP, but at a lower effluent limit (0.3 mg/L TP).

**Table 7-11. Progressive TP Reduction Scenarios at Station 4ALOR014.33**

Land Use / Source Groups	Units	Future TP Load	BMP Scenario 1	BMP Scenario 2	Allocation Scenario 1	Allocation Scenario 2
Row Crops	(lbs/yr)	4.9	4.9	4.9	4.9	4.9

<b>Total TP Load</b>		<b>10,077.2</b>	<b>9,561.0</b>	<b>9,077.1</b>	<b>3,516.3</b>	<b>3,820.9</b>
Total Flow Volume	(L x 10 <sup>6</sup> /yr)	23,687.3	23,475.3	23,466.3	23,466.3	24,850.7
<b>Average TP Concentration</b>	(mg/L)	<b>0.193</b>	<b>0.185</b>	<b>0.175</b>	<b>0.068</b>	<b>0.070</b>

BMP Scenario 1 = Future Load + all Big Otter River IP BMPs.

BMP Scenario 2 = BMP Scenario 1 + all Little Otter River sediment TMDL reductions.

Allocation Scenario 1 = BMP Scenario 2 + WWTP at current flow (1.0 MGD) and 0.5 mg/L TP effluent limits.

Allocation Scenario 2 = BMP Scenario 2 + WWTP at design flow (2.0 MGD) and 0.3 mg/L TP effluent limit.

## **Chapter 8: TMDL IMPLEMENTATION**

The goal of the TMDL program is to establish a three-step path that will lead to attainment of water quality standards. The first step in the process is to develop TMDLs that will result in meeting water quality standards. This report represents the culmination of that effort for the benthic impairments on Buffalo Creek, Johns Creek, Wells Creek, and the Little Otter River. The second step is to develop a TMDL Implementation Plan. The final step is to implement the TMDL Implementation Plan and to monitor stream water quality to determine if water quality standards are being attained.

Once a TMDL has been approved by USEPA and then the State Water Control Board (SWCB), measures must be taken to reduce pollutant levels in the stream. These measures, which can include the use of better treatment technology and the installation of BMPs, are implemented in an iterative process that is described along with specific BMPs in the Implementation Plan. The process for developing an Implementation Plan has been described in the “TMDL Implementation Plan Guidance Manual”, published in July 2003 and available upon request from the DEQ and DCR TMDL project staff or at <http://www.deq.virginia.gov/Portals/0/DEQ/Water/TMDL/ImplementationPlans/ipguide.pdf>. With successful completion of Implementation Plans, Virginia begins the process of restoring impaired waters and enhancing the value of this important resource. Additionally, development of an approved Implementation Plan will improve a locality's chances for obtaining financial and technical assistance during implementation.

Watershed stakeholders will have opportunity to participate in the development of the TMDL Implementation Plan, which is the next step in the TMDL process. Specific goals for BMP implementation will be established as part of the Implementation Plan development. DCR and DEQ will work closely with watershed stakeholders, interested state agencies, and support groups to develop an acceptable Implementation Plan that will result in meeting the water quality target. Stream delisting of Buffalo Creek and Little

Otter River impaired stream segments will be based on biological health and not on numerical pollution loads.

## **8.1. Link to ongoing Restoration Efforts**

Implementation of BMPs to address the benthic impairments in Buffalo Creek and Little Otter River will be coordinated with BMPs required to meet bacteria water quality standards in a previous TMDL developed for the Big Otter River watershed, which includes both Buffalo Creek and Little Otter River.

## **8.2. Reasonable Assurance for Implementation**

### **8.2.1. TMDL Monitoring**

DEQ will monitor benthic macro-invertebrates and habitat in accordance with its biological monitoring program, and TSS in accordance with its ambient monitoring program at station 4ALOR014.75 in the Upper Little Otter River, at station 4AJHN000.01 in Johns Creek, at station 4AWEL001.14 in Wells Creek, at station 4ALOR014.33 in the Lower Little Otter River, at station 4ABWA008.53 in the Upper Buffalo Creek, and at station 4ABWA002.00 in the Lower Buffalo Creek. In the past, all of these stations have been used for both biological and ambient sampling, with the exception of stations 4ALOR014.33 and station 4ABWA008.53 which were monitored regularly for benthic macro-invertebrates and habitat, but only periodically for ambient parameters. DEQ will add bi-monthly sampling of ambient TSS at these two stations and will continue to use data from all of these monitoring stations to evaluate improvements in the benthic community and the effectiveness of TMDL implementation in attainment of the general water quality standard.

DEQ will also continue monitoring TP at the three stations upstream and downstream from the WWTP (4AJHN000.01, 4ALOR014.75, and 4ALOR014.33) and include monthly TP monitoring requirements in future permit renewals for the Bedford City WWTP.

## **8.2.2. Regulatory Framework**

### Federal Regulations

While section 303(d) of the Clean Water Act and current USEPA regulations do not require the development of TMDL implementation plans as part of the TMDL process, they do require reasonable assurance that the load and wasteload allocations can and will be implemented. Federal regulations also require that all new or revised National Pollutant Discharge Elimination System (NPDES) permits must be consistent with the assumptions and requirements of any applicable TMDL WLA (40 CFR §122.44 (d)(1)(vii)(B)). All such permits should be submitted to USEPA for review. New effluent discharge limits will be set through the VPDES permit process to reduce TP loads from the one municipal discharger in the Little Otter River watershed.

### State Regulations

Additionally, Virginia's 1997 Water Quality Monitoring, Information and Restoration Act (WQMIRA) directs the State Water Control Board to "develop and implement a plan to achieve fully supporting status for impaired waters" (Section 62.1-44.19.7). WQMIRA also establishes that the implementation plan shall include the date of expected achievement of water quality objectives, measurable goals, corrective actions necessary and the associated costs, benefits and environmental impacts of addressing the impairments. USEPA outlines the minimum elements of an approvable implementation plan in its 1999 "Guidance for Water Quality-Based Decisions: The TMDL Process." The listed elements include implementation actions/management measures, timelines, legal or regulatory controls, time required to attain water quality standards, monitoring plans and milestones for attaining water quality standards.

For the implementation of the WLA component of the TMDL, the Commonwealth utilizes the Virginia NPDES program, which typically includes consideration of the WQMIRA requirements during the permitting process. Requirements of the permit process should not be duplicated in the TMDL process and implementation plan development, especially those implemented through water quality based effluent limitations. However, those requirements that are considered BMPs may be enhanced by inclusion in the TMDL IP, and their connection to the identified impairment. New

permitted point source discharges will be allowed under the waste load allocation provided they implement applicable VPDES requirements.

### **8.2.3. Implementation Funding Sources**

Implementation funding sources will be determined during the implementation planning process by the local watershed stakeholder planning group with assistance from DEQ and DCR. Potential sources of funding include Section 319 funding for Virginia's Nonpoint Source Management Program, the U.S. Department of Agriculture's Conservation Reserve Enhancement and Environmental Quality Incentive Programs, the Virginia State Revolving Loan Program, and the Virginia Water Quality Improvement Fund, although other sources are also available for specific projects and regions of the state. The TMDL Implementation Plan Guidance Manual contains additional information on funding sources, as well as government agencies that might support implementation efforts and suggestions for integrating TMDL implementation with other watershed planning efforts.

### **8.2.4. Existence of an Encompassing TMDL Implementation Plan**

A TMDL Implementation Plan currently exists for the Big Otter River, which encompasses the Little Otter River and Buffalo Creek (VT-BSE, 2006). Implementation of BMPs to address the benthic impairments in Buffalo Creek and Little Otter River will be coordinated with BMPs required to meet bacteria water quality standards in a previous TMDL developed for the Big Otter River watershed, which includes both Buffalo Creek and Little Otter River.

### **8.2.5. Reasonable Assurance Summary**

Watershed stakeholders will have opportunities to provide input and to participate in the development of the implementation plan, which will also be supported by regional and local offices of DEQ, DCR, and other cooperating agencies.

Once developed, DEQ intends to incorporate the TMDL implementation plan into the appropriate Water Quality Management Plan (WQMP), in accordance with the Clean Water Act's Section 303(e). In response to a Memorandum of Understanding (MOU) between USEPA and DEQ, DEQ also submitted a draft Continuous Planning Process to USEPA in which DEQ commits to regularly updating the WQMPs. Thus, the WQMPs

will be, among other things, the repository for all TMDLs and TMDL implementation plans developed within a river basin.

Taken together, the follow-up monitoring, WQMIRA, public participation, the Continuing Planning Process, planned new industrial discharge permitting, and the reductions called for in the concurrent bacteria TMDL on the Big Otter River comprise a reasonable assurance that the Buffalo Creek, Johns Creek, Wells Creek, and Little Otter River sediment TMDLs and the Lower Little Otter River total phosphorus TMDL will be implemented and water quality will be restored.

## **Chapter 9: PUBLIC PARTICIPATION**

Public participation was elicited at every stage of the TMDL development in order to receive inputs from stakeholders and to apprise the stakeholders of the progress made.

The first Technical Advisory Committee Meeting was held from 10:00 am until noon on June 21, 2012 at the Bedford Central Library in Bedford, Virginia. The purpose of that meeting was to introduce agency stakeholders to the TMDL process and to discuss the impairments identified on stream segments in these watersheds. The public meeting was attended by 19 people. Many of the attendees reconvened after lunch to participate in a watershed tour, conducted by personnel from the Peaks of Otter Soil and Water Conservation District and NRCS personnel.

The first Public Meeting was held at 7:00 - 9:00 pm at the Forest Library in Forest, Virginia on August 14, 2012, where the TMDL process was introduced, local stream impairments were presented, and comments were solicited from the stakeholder group. The first public meeting was attended by 18 people.

A second Technical Advisory Committee meeting was held from 2:00 - 4:00 pm on October 18, 2012, at the Bedford Central Library in Bedford. The results from the stressor analysis were presented, and comments were solicited from the stakeholder group. The second TAC meeting was attended by 9 people.

A third Technical Advisory Committee meeting was held on February 7, 2013 to present modeling procedures, draft modeling results, and to solicit feedback on the proposed TMDL strategy.

A final public meeting was held on February 20, 2013 to present the draft TMDL report to address benthic impairments in the Little Otter River and Buffalo Creek watersheds. This final TMDL public meeting was attended by 23 stakeholders. The public comment period will end on March 22, 2013.

Since the TP TMDL for the Lower Little Otter River was developed after the final public meeting mentioned above, in lieu of remediation strictly through the permit

process, another local Technical Advisory Committee was held on January ??, 2014 to present the findings to key members of the watershed group, including representatives from the Bedford City municipal authority and to obtain feedback. This revised report, which includes the TP TMDL, will be distributed by email to all past attendees of public meetings and will be posted on DEQ's web site to solicit any additional public comments. The public comment period will end on February ??, 2014.

## **Appendix A: Glossary of Terms**

### **Allocation**

That portion of a receiving water's loading capacity that is attributed to one of its existing or future pollution sources (nonpoint or point) or to natural background sources.

### **Allocation Scenario**

A proposed series of point and nonpoint source allocations (loadings from different sources), which are being considered to meet a water quality planning goal.

### **Background levels**

Levels representing the chemical, physical, and biological conditions that would result from natural geomorphological processes such as weathering and dissolution.

### **Best Management Practices (BMP)**

Methods, measures, or practices that are determined to be reasonable and cost-effective means for a land owner to meet certain, generally nonpoint source, pollution control needs. BMPs include structural and nonstructural controls and operation and maintenance procedures.

### **Hydrology**

The study of the distribution, properties, and effects of water on the earth's surface, in the soil and underlying rocks, and in the atmosphere.

### **Load allocation (LA)**

The portion of a receiving water's loading capacity that is attributed either to one of its existing or future nonpoint sources of pollution or to natural background.

### **Margin of Safety (MOS)**

A required component of the TMDL that accounts for the uncertainty about the relationship between the pollutant loads and the quality of the receiving waterbody. The MOS is normally incorporated into the conservative assumptions used to develop TMDLs (generally within the calculations or models). The MOS may also be assigned explicitly, as was done in this study, to ensure that the water quality standard is not violated.

### **Model**

Mathematical representation of hydrologic and water quality processes. Effects of Land use, slope, soil characteristics, and management practices are included.

### **Nonpoint source**

Pollution that is not released through pipes but rather originates from multiple sources over a relatively large area. Nonpoint sources can be divided into source activities related to either land or water use including failing septic tanks, improper animal-keeping practices, forest practices, and urban and rural runoff.

### **Point source**

Pollutant loads discharged at a specific location from pipes, outfalls, and conveyance channels from either municipal wastewater treatment plants or industrial waste treatment facilities. Point sources can also include pollutant loads contributed by tributaries to the main receiving water stream or river.

**Pollution**

Generally, the presence of matter or energy whose nature, location, or quantity produces undesired environmental effects. Under the Clean Water Act for example, the term is defined as the man-made or man-induced alteration of the physical, biological, chemical, and radiological integrity of water.

**Reach**

Segment of a stream or river.

**Runoff**

That part of rainfall or snowmelt that runs off the land into streams or other surface water. It can carry pollutants from the air and land into receiving waters.

**Simulation**

The use of mathematical models to approximate the observed behavior of a natural water system in response to a specific known set of input and forcing conditions. Models that have been validated, or verified, are then used to predict the response of a natural water system to changes in the input or forcing conditions.

**Total Maximum Daily Load (TMDL)**

The sum of the individual wasteload allocations (WLA's) for point sources, load allocations (LA's) for nonpoint sources and natural background, plus a margin of safety (MOS). TMDLs can be expressed in terms of mass per time, toxicity, or other appropriate measures that relate to a state's water quality standard.

**Urban Runoff**

Surface runoff originating from an urban drainage area including streets, parking lots, and rooftops.

**Wasteload allocation (WLA)**

The portion of a receiving water's loading capacity that is allocated to one of its existing or future point sources of pollution. WLAs constitute a type of water quality-based effluent limitation.

**Water quality standard**

Law or regulation that consists of the beneficial designated use or uses of a water body, the numeric and narrative water quality criteria that are necessary to protect the use or uses of that particular water body, and an anti-degradation statement.

**Watershed**

A drainage area or basin in which all land and water areas drain or flow toward a central collector such as a stream, river, or lake at a lower elevation.

## **Appendix D: Model Calibration**

### **D.1. Hydrology**

Model calibration is the process of adjusting model parameter values so that simulated loads from a watershed match loads calculated from corresponding monitored (“observed”) flow and concentrations at a given point in a stream. Although GWLF was originally developed for use in non-gaged watersheds and, therefore, does not require calibration, hydrologic calibration has been recommended where observed flow data is available (Dai et al., 2000). In-stream observed discharge data were not available in any of the Little Otter River or Buffalo Creek sub-watersheds, but were available in a similar-sized neighboring watershed, the Big Otter River. Hydrologic calibration was performed using this surrogate watershed, and the calibration adjustments applied to all of the Little Otter River, Buffalo Creek and comparison watersheds for the TMDL modeling.

The purpose of calibration was to adjust parameter values within the model so that simulated model output more closely matched observed data. By calibrating to total flow and seasonal flow distribution, simulation of the hydrology-dependent sediment load components should also be more representative of watershed conditions.

Daily discharge records were available at the USGS station 0206100 on the Big Otter River, adjacent to the Little Otter River, from December 2006 through the present. A model of the Big Otter River was constructed as discussed previously and discharge simulated for the 4-yr calibration period, January 2008 through December 2011. Observed monthly discharge was then compared with GWLF simulated flow for the surrogate watershed.

GWLF uses daily rainfall inputs and generates monthly runoff outputs. Hydrologic calibration was performed based on monthly runoff (flow) totals. The parameters adjusted during hydrologic calibration included the recession coefficient, the seepage coefficient, the leakage coefficient, the soil available water content (AWC), and area-weighted dormant- and growing-season ET cover coefficients.

Spreadsheets were constructed and used to analyze model output after each model run, and to calculate parameter adjustments for the next iteration of calibration. Within the spreadsheets, comparisons were made between simulated and observed runoff for the flow components, seasonal distribution, monthly runoff time series, and cumulative runoff. Total flow was calibrated through adjustments to the seepage and leakage coefficients, while seasonal distribution was calibrated by adjusting the area-weighted dormant-season ET cover coefficients.

The results of the hydrologic calibration for Big Otter River are presented as a monthly runoff time series in Figure D-1, cumulative runoff in Figure D, and flow and seasonal distributions in Table D.

**Figure D-1. Calibration Monthly Runoff Time Series - Big Otter River**

**Figure D-2. Calibration Cumulative Runoff - Big Otter River**

**Table D-1. Calibration Flow Distributions - Big Otter River - 2008-2011**

Flow Distribution Components	SIMULATED		OBSERVED		Sim-Obs	
	(cm/yr)	(% of Total)	(cm/yr)	(% of Total)	(cm/yr)	(% of Total)
Total Runoff	29.83		29.69		0.14	0.5%
Total Surface Runoff	7.26	24.3%				
Total Baseflow	22.57	75.7%		67.0%		11.5%
Winter (Dec-Feb) Runoff	11.25	37.7%	10.52	35.4%	0.73	7.0%
Spring (Mar-May) Runoff	9.40	31.5%	11.05	37.2%	-1.66	-15.0%
Summer (Jun-Aug) Runoff	2.86	9.6%	3.51	11.8%	-0.66	-18.7%
Fall (Sep-Nov) Runoff	6.33	21.2%	4.60	15.5%	1.73	37.5%

The monthly runoff time series for Big Otter River showed a generally good correspondence between observed and simulated monthly runoff, with a correlation coefficient of 0.89. The simulated seasonal percentages of runoff varied up to 38% of the observed values (mainly due to a mismatch of observed and simulated data in September 2010), although total simulated runoff was only 0.5% less than the observed value. The difference between observed and simulated individual season average annual discharge totals were within  $\pm 1.73$  cm/season, and the baseflow percentage was within 11.5% of observed baseflow, calculated using the baseflow separation routine of Arnold et al. (1995). Since the TMDL is based on long-term average annual loads and uses comparably parameterized watersheds, the calibrated GWLF model should provide reasonable load comparisons for TMDL development.

In order to further ascertain the appropriateness of the calibrated model for Little Otter River and Buffalo Creek, a variety of average annual metrics were calculated from simulated outputs for the wider range of precipitation inputs to the model as used for TMDL modeling and shown in Table D. These are compared with observed or modeled outputs from other watersheds or monitoring gages in the region. Precipitation input for the watersheds modeled in the current TMDLs are slightly higher than those used in three previous TMDLs in the Shenandoah Valley. Simulated evapotranspiration is therefore slightly higher, as would be expected from larger precipitation inputs. Surface runoff - amount and % of total precipitation - fall within the range of the previous TMDLs. Surface runoff was larger for Abrams Creek, as would be expected from a highly urbanized area. The area-normalized flows are comparable between the current TMDL

watersheds and the calibration watershed, as baseflow % was one of the measures used to guide calibration, and within the larger range seen in previous TMDLs. All in all, the calibrated Little Otter River and Buffalo Creek hydrology appear to be reasonable for this region.

**Table D-2. Simulated Metrics Compared with Regional Watersheds**

	Current TMDLs		USGS Flow	Previous TMDLs		
	Buffalo Creek	Little Otter River	Big Otter River	Abrams Creek	Toms Brook	Mossy Creek
<b>Annual Average Values</b>						
Watershed Area (sq.mi.)	25.6	67.7	127.4	19.1	16.4	14.7
Averaging Period	1992-2010	1992-2010	2007-2011	1982-1987	1985-1994	1985-1999
Precipitation (cm/yr)	106.1	113.9		93.2	93.56	96.91
Evapotranspiration (cm/yr)	67.3	68.3		48.0	62.7	45.1
Surface runoff (cm/yr)	8.0	9.4		17.0	5.8	5.7
Surface runoff (% of precipitation)	7.5%	8.3%		18.2%	6.2%	5.8%
Area-normalized Flow (cfs/m)	0.78	0.87	0.83	0.97	0.90	1.32
Baseflow (% of Total Streamflow)	70.5%	68.4%	67.0%	61.9%	81.4%	89.1%

## **D.2. Total Phosphorus**

The following is a description of the watershed configuration used for simulation of total phosphorus loads to the Lower Little Otter River. The primary source of elevated TP concentrations at the most upstream station on the Lower Little Otter River (4ALOR014.33) is the Bedford County WWTP. The WWTP outfall (River Mile 14.36) is exactly at the confluence of Johns Creek and the Upper Little Otter River watersheds whose discharge is not measured by stations in either of these two upstream watersheds. The downstream station is situated only 0.03 miles below the confluence of Johns Creek and the Upper Little Otter River, Figure D-3. Since the amount of land draining to station 4ALOR014.33 is only 2.5 acres of primarily forest and hay land with no obvious unusual sources of nutrients, the TP loads and calculated concentrations at station 4ALOR014.33 were represented simply as the sum of loads from the Johns Creek (JHN) and Upper Little Otter River (LOR2) watersheds at their confluence plus the loads from the WWTP. The loads to the impaired segment of the Lower Little Otter River, as assessed at station 4ALOR014.33, therefore, are simulated solely as in-stream loads delivered from upstream.

**Figure D-3. Watershed Configuration for TP Calibration and Simulation**

Average simulated TP loads and flows were used to calculate average TP concentrations from the JHN and LOR2b watersheds, respectively, which were then calibrated to average observed TP concentrations at stations 4AJHN000.01 and 4ALOR014.75, respectively. The simulation period was from 2004 through 2011. Calibration was performed by scaling initial estimates of loading function rates for various modeling components, until the average calculated simulated concentration matched the average observed value at each station. The period and number of observed samples varied between stations, as shown in Table D-3 for the JHN watershed and Table D-4 for the LOR2b watershed. Each table shows the simulated and observed averages and ranges of monthly concentrations, as well as the number of observed samples and period of sampled record.

**Table D-3. Calibrated Ranges and Averages of total nitrogen (TN) and total phosphorus (TP) in the Johns Creek Watershed (JHN)**

Simulated Period of Analysis: Jan-04 through Dec-11 (8 years)				
JHN @ Station 4AJHN000.01				
	TN (mg/L)		TP (mg/L)	
	observed	simulated	observed	simulated
minimum	0.190	0.200	0.020	0.012
average	0.525	0.532	0.050	0.050
maximum	0.820	1.878	0.080	0.241
n	4		4	
Observed Period	May-09 through Nov-11		May-09 through Nov-11	

**Table D-4. Calibrated Ranges and Averages of total nitrogen (TN) and total phosphorus (TP) in the Upper Little Otter Watershed (LOR2b)**

Simulated Period of Analysis: Jan-04 through Dec-11 (8 years)				
LOR2b @ Station 4ALOR014.75				
	TN (mg/L)		TP (mg/L)	
	observed	simulated	observed	simulated
minimum	0.260	0.488	0.020	0.014
average	0.881	0.882	0.072	0.072
maximum	1.700	1.868	0.300	0.282
n	32		32	
Observed Period	Feb-07 through Apr-12		Feb-07 through Apr-12	

As a further check on the calibration, loads were simulated for the entire watershed and average TP concentrations calculated at station 4ALOR014.33 and compared with the two available observed values at that station. First, the calibrated parameters from LOR2b were applied to the entire LOR2 watershed. Then loads and flows were simulated for JHN and LOR2b and calculated from the WWTP, and finally total simulated TP loads were divided by total simulated flow to calculate an average simulated TP concentration for comparison with the observed average at station 4ALOR014.33. The results are shown in Table D-5.

**Table D-5. Validation Check at Downstream Station 4ALOR014.33**

Simulated Period of Analysis: Jan-04 through Dec-11 (8 years)				
LOR2 @ Station 4ALOR014.33				
	TN (mg/L)		TP (mg/L)	
	observed	simulated	observed	simulated
minimum	2.64	0.89	0.320	0.090
average	3.41	1.65	0.440	0.199
maximum	4.17	11.06	0.560	1.676
n	2		2	
Observed Period	Jun-11 and Nov-11		Jun-11 and Nov-11	

The resulting concentrations calculated from the summed simulated loads and flows are much lower, though the ranges of monthly average concentrations do include the observed values. After realizing that the observed averages at station 4ALOR014.33 are based on only 2 samples from the later part of the simulated period, simulated loads and calculated concentrations were investigated for months corresponding to the two observed samples, as shown in Table D-6.

**Table D-6. Comparison of Observed and Average Monthly Simulated TP Concentrations at 4ALOR014.33**

Period	Observed	Simulated
2004-2011 Average	--	0.199
Jun-11	0.560	0.699
Nov-11	0.320	0.151

This comparison shows that the simulated monthly concentrations do vary considerably and that the simulated concentrations in any given month reflect the seasonal flow and loading combinations available at that time. The Jun-11 sample, in particular, shows that the simulated values at that given point in time are considerably above the overall simulated average and at a comparable level to the observed values in that one sample. This is typical of summer months when total flows are typically lower, thereby increasing the influence of the load from the WWTP, as seen in Table D-7. Therefore, this overall calibration looks reasonable and consistent with the observed data.

**Table D-7. Average Simulated Monthly Flows and Concentrations at 4ALOR014.33, 2004-2011**

Month	Flow/Volume (10 <sup>6</sup> L/yr)	TN Load (kg/yr)	TP Load (kg/yr)	TN conc (mg/L)	TP conc (mg/L)
January	31.291.0	42,170.2	4,818.5	1.35	0.157

## **Appendix E: GWLF Model Parameters**

The GWLF parameter values used for the Little Otter River and Buffalo Creek watershed simulations are shown in Table E-1 through Table E-3. Table E-1 lists the various watershed-wide parameters and their values, Table E-2 displays the monthly variable evapo-transpiration cover coefficients, and Table E-3 shows the land use-related parameters - runoff curve numbers (CN) and the Universal Soil Loss Equation's KLSCP product - used for erosion modeling. Calibrated parameters and their calibrated values are indicated in each of the tables. Corresponding GWLF parameter values for the comparison and calibration watersheds are shown in Table E-4 through Table E-6. Table E-7 includes the values and ranges of total phosphorus loading function parameter values used for TP modeling in Johns Creek and Upper Little Otter River. Since the modeling was performed in metric units, note that all of the input parameters are in metric units, even though the simulated results shown in this report are presented in English units.

**Table E-1. GWLF Watershed Parameters for Little Otter River and Buffalo Creek**

## Appendix F: Setting TMDL Endpoints and MOS using the AllForX Approach

In the AllForX approach, introduced in Chapter 4, the metric used for setting a numeric sediment threshold is the All-Forest Load Multiplier (AllForX) calculated as the existing sediment load normalized by the corresponding load under an all-forest condition. AllForX is calculated as the existing sediment load in any given watershed divided by the corresponding sediment load simulated under an all-forest condition. When AllForX is regressed against VSCI for a number of healthy watersheds surrounding a particular TMDL watershed or set of TMDL watersheds, the developed relationship can be used to quantify the value of AllForX for the biological health threshold (VSCI < 60) used to assess aquatic life use impairments in Virginia. The sediment TMDL load is then calculated as the value of AllForX at the VSCI threshold times the all-forest sediment load of the TMDL watershed. Since a number of watersheds are used to quantify the regression, a confidence interval around the threshold was used to quantify the margin of safety in the Total Maximum Daily Load equation.

Existing sediment loads were calculated for each of the TMDL watersheds contributing to the six (6) impaired segments in this study and for each of the four (4) comparison watersheds. A modeling scenario was then created and run, which substituted forest land use-related parameters for each of the other land uses, while preserving the unique characteristics of soil and slope distributions across each watershed. AllForX was then calculated by dividing the existing sediment load by the all-forest load. The modeling results for each watershed are summarized as long-term averages for each watershed in Table F-1.

**Table F-1. Metrics used in the AllForX Approach**

Land Use/Source Categories	BWA1	BWA2	LOR1	WEL	JHN	LOR2	BLD	BNF	CNT	GCR
	Sediment Load in metric tons/yr									
Existing Sediment Load	3,058.0	1,449.1	8,643.2	3,137.8	559.1	6,382.4	22,500.0	428.8	7,241.2	892.1
All-Forested Sediment Load	265.3	64.9	697.8	80.8	32.5	232.6	<b>2,912.9</b>	<b>361.6</b>	<b>1,003.7</b>	<b>440.3</b>
AllForX*	<b>11.5</b>	<b>22.3</b>	<b>12.4</b>	<b>38.8</b>	<b>17.2</b>	<b>27.4</b>	<b>7.7</b>	<b>1.2</b>	<b>7.2</b>	<b>2.0</b>
Average VSCI	<b>58.4</b>	<b>42.7</b>	<b>48.0</b>	<b>50.5</b>	<b>48.0</b>	<b>55.3</b>	<b>67.3</b>	<b>77.7</b>	<b>68.2</b>	<b>75.2</b>

A regression between AllForX and VSCI was developed using all ten (10) watersheds, as shown in Figure F-1. The value of AllForX used to set the sediment TMDL load was the value where the regression line crossed the biological impairment threshold of VSCI = 60 (AllForX = 13.64), indicated by point B. The TMDL load for each watershed was calculated as its All-Forest sediment load times the threshold AllForX value (13.64). An 80% confidence interval was then calculated around the point where the regression line intersects the biological impairment threshold (VSCI = 60). The margin of safety (MOS) was calculated as the All-Forest sediment load times the difference in AllForX between the point where the regression crosses VSCI = 60 (AllForX = 13.64) and the lower bound of the 80% confidence interval (AllForX = 11.17). Note that the MOS is equal to this difference expressed as a percentage of the threshold AllForX, and therefore is the same for all watersheds using this regression. Existing, TMDL, and MOS loads are shown in Table F-2 for each TMDL watershed. Since the MOS is a measure of uncertainty in the TMDL, the implementation target load is the TMDL minus the MOS, and the percent reduction is calculated as the change from the future load to the allocation target load.

B = AllForX value used for the TMDL; AC = the 80% Confidence Interval (shown in green);  
 B - A = AllForX value used for the MOS; A = AllForX value used for the target allocation load.

**Figure F-1. Regression and AllForX Threshold for Sediment in Little Otter and Buffalo Creek**

**Table F-2. Calculation of the TMDL and MOS for each TMDL Watershed**

	<b>TMDL Watersheds</b>					
	<b>BWA1</b>	<b>BWA2</b>	<b>LOR1</b>	<b>WEL</b>	<b>JHN</b>	<b>LOR2</b>
	Sediment Load in metric tons/yr

MOS as % of TMDL	18.1%	18.1%	18.1%	18.1%	18.1%	18.1%
<b>Allocation Load (TMDL - MOS)</b>	<b>2,963.0</b>	<b>724.4</b>	<b>7,793.1</b>	<b>902.7</b>	<b>363.2</b>	<b>2,598.2</b>
% Reduction from Future Load:	11.1%	51.1%	9.8%	71.2%	35.0%	55.2%

The relationship between AllForX and the biological condition was further validated with the following plots and regressions between AllForX and various independent sediment-related habitat metrics: average habitat sediment deposition in Figure F-2; average epifaunal substrate in Figure F-3; and total habitat score in Figure F-4.

**Figure F-2. AllForX vs. Average Habitat Sediment Deposition Scores**

**Figure F-3. AllForX vs. Average Habitat Epifaunal Substrate Scores**

**Figure F-4. AllForX vs. Average Total Habitat Scores**
